Terms for Position Pages and Serial Insertions on application.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to fictitious names or initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials &c. sent to the Office in reply to advertisements; copies only should be forwarded.

Terms for Serial Insertions may be obtained of the Manager, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom.

Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

The Milroy Lectures

ON

THE NATURAL HISTORY AND AFFINITIES
OF RHEUMATIC FEVER: A STUDY IN
EPIDEMIOLOGY.*Delivered at the Royal College of Physicians of London on
March 5th, 7th, 12th, and 14th, 1895,*

By ARTHUR NEWSHOLME, M.D. LOND.,

MEDICAL OFFICER OF HEALTH OF BRIGHTON.

LECTURE III.¹*Delivered on March 12th.*

THE INFLUENCE OF AIR AND EARTH TEMPERATURE.

MR. PRESIDENT AND GENTLEMEN,—To ascertain whether the temperature of the air or soil has any essential relationship with the origin of rheumatic fever we must learn whether variations in temperature are accompanied by variations in the prevalence of the disease, and whether modifications in these seasonal changes of temperature are accompanied by corresponding modifications in the amount of rheumatic fever. Taking the mean annual temperature at Greenwich since 1866, we find that in 1866 and in 1868-69, years in which rheumatic fever was excessive in London, the mean temperature was from 1 to 5 per cent. above the mean for the whole period 1866-93; in 1874-75, which were epidemic years, it was at the mean line. In 1879, a minimum year for rheumatic fever, the mean temperature was also low (6 per cent. below the mean), and in 1884, with a temperature 4 per cent. above the mean, rheumatic fever was again excessive. In 1893 there was the same association of high temperature and excessive rheumatic fever. On the whole, therefore, it would appear that a high temperature is in England favourable to an increase of rheumatic fever, though the experience of 1874-75 shows that there is no definite proportion between the two. In order to exhaust the possibilities as to the influence of the temperature of the air, the weekly maximum and minimum temperatures in 1874-75 were contrasted with the corresponding weekly admissions to Guy's and St. George's Hospitals for rheumatic fever, with no more definite result than could have been inferred from the statements already made as to the seasonal distribution of rheumatic fever. In 1893, owing to the marked drought in the second quarter of the year, the atmospheric conditions were exceptional, but a comparison of these with the weekly admissions to Guy's Hospital during the same period shows no such marked variations as might have been expected if atmospheric temperature were a very pronounced element in the causation of rheumatic fever.

Records of the temperature of the earth, so far as they are obtainable, show that in years in which rheumatic fever is exceptionally prevalent the earth temperature is unusually high. From a record of the temperature of the soil at 9 A.M. at four feet below the surface, kept at Regent's Park since 1871, I have been able to obtain the mean earth temperature for every year since 1871 excepting 1877-79, and the maximum and minimum temperatures since 1880. The record shows that in 1871-74 inclusive the mean earth temperature of the year was always at or above 50° F., a temperature which was not again reached except in 1884 and 1893 (which were also epidemic years). In 1875 the mean earth temperature was 49.4° and in 1876 it was 49.7°, temperatures which were not equalled except in 1882 and 1883 and in 1894. A comparison of the extreme with the mean temperatures of the earth, and of the mean temperature of the earth in 1871-76 with the corresponding mean temperatures in later years, shows that during the period in which comparison is possible in London great epidemics of rheumatic fever occur only when the mean temperature of the soil is exceptionally high—i.e., over 50° F.—and that the greatest epidemics occur when the mean temperature has been thus high for two or more years in succession.

Humidity of air may be similarly tested. On plotting

out the mean dew-point temperature of the first and fourth quarters of each year there is no consistent result, the indications pointing in opposite directions both in epidemic and non-epidemic years. No relationship can be traced for the years 1874 and 1875 between the weekly admissions to Guy's and St. George's Hospitals, London, and the dryness of the air as indicated by the difference between the dew-point temperature and the air temperature in the corresponding or the preceding weeks. It would be unwise to conclude that the meteorological factors just mentioned have no influence. Hospital patients with rheumatic fever are not admitted until a variable period from the onset of their illness. Gull and Sutton give the average duration before admission as nine days. Then, again, we do not know how soon the climatic conditions, if operative, produce rheumatic fever, or, accepting the infective theory, we do not know the period of incubation of the disease. It is possible that daily observations of barometric pressure if compared with the daily number of cases of rheumatic fever would furnish valuable indications; but these will be impracticable in this country until or unless a general system of notification of the disease is introduced. Mean barometric pressures for weeks or months have comparatively little value, as they give but a feeble notion of the range of pressure, which is the all-important point.

THE INFLUENCE OF RAINFALL.

Rainfall might be expected to have a much closer association with the prevalence of rheumatic fever than any other meteorological condition, as it has become almost accepted as an axiom in medicine that damp air and damp soil are provocative of rheumatic fever. Even on this point the observations, as summarised by Dr. A. E. Garrod in his "Treatise on Rheumatism," are hopelessly at variance. Hirsch at Würzburg and Edlefsen at Kiel found that the amount of rheumatic fever was inversely as the rainfall, while the report of the Collective Investigation Committee of the British Medical Association shows that most cases begin in damp or wet, or cold or cloudy weather; and Dr. Gabbett² on the strength of the London Hospital statistics for 1873-81 says there is, if anything, a tendency for the prevalence of rheumatic fever to vary directly with the rainfall. Dr. Longstaff³ classifies rheumatic fever with scarlet fever, erysipelas, &c., as a "dry disease"—i.e., checked by rainfall, especially frequent rainfall.

Observations on rainfall in London.—In 1867 the rainfall at Greenwich was 17 per cent. above the average, and in 1868 4 per cent. above the average, and yet 1868 was marked by a large epidemic. In 1870 with a deficiency of 25 per cent. of rainfall there was a smaller epidemic, and in 1874 a large epidemic of rheumatic fever corresponded with a small rainfall, the epidemic continuing in 1875 although the rainfall was in that year 12 per cent. above the average; 1872 and 1879 with the highest rainfalls in the whole period had a small amount of rheumatic fever. The relationship may be examined more closely in the rainfall for each quarter, but this does not appear to alter the rule that may be laid down that a heavy annual rainfall is usually associated with a low amount of rheumatic fever, and a small rainfall with a large amount of rheumatic fever, though there is no exact proportion observable between the two. It is certain, however, that two or three years of deficient or excessive rainfall are more potent than a single year. The rainfall of Hertfordshire is recorded for a very long period, arranged in a manner very convenient for our present purpose;⁴ it is here employed, therefore, for comparison with the annual amount of rheumatism in London as well as that at Greenwich. It will be seen that in 1861-2-3-4 the rainfall was much below the average, and that the deaths from rheumatism in London, which had begun to increase in 1862, were still more excessive in 1863-4-5. In 1865 the rainfall reached its next maximum, but the deaths from rheumatism did not reach their minimum until 1867. In 1868, when rheumatism was again in excess, rainfall was about the average amount, as also in 1867. In 1873-4 with deficient rainfall there was an increasing amount of rheumatism, which culminated in 1875 although in that year the rainfall was excessive. In 1881, 1884, 1887, and 1890 small rainfall corresponded with minor increases of rheumatism. The summer (April to September) and winter (October to March) ratios of rainfall

¹ THE LANCET, Oct. 20th, 1893.² Studies in Statistics, p. 370.⁴ Appendix to Report of Royal Commission on Metropolitan Water-supply.¹ Lectures I. and II. appeared in THE LANCET of March 9th, 1895. No. 3733.

for Herts confirm the results of the years' ratios. With an excess of rheumatism both winter and summer ratios of rainfall were nearly always below the average. Observation of the number of rainy days in each year confirms the preceding results. In only one instance was the number of rainy days above the average in a year in which the deaths from rheumatism in London were slightly excessive—viz., in 1890. The inquiry may be pursued in other places besides London. In Brighton the rainfall in 1873 and 1874 was much below the average; in 1875 it was 1 per cent. above the average. In 1874-75 occurred a large epidemic of rheumatic fever. From 1877-81 rainfall was above the average, and so was the rheumatic fever in three out of the four years. In 1884, again, there were deficient rainfall and little rheumatic fever. In 1888 there was a large amount of rheumatic fever; the rainfall was a little below the average. In 1891 very little rainfall and excessive rheumatic fever. In 1893 a small increase of rheumatic fever, with deficient rainfall.

At Glasgow the record of rainfall is unfortunately broken at intervals, but it is possible to form a fairly accurate idea from the separate curves for the rainfall of each quarter of the year. Thus 1873 and 1874 were epidemic years. In 1873 the rainfall was at or above the mean line in the first three quarters, and only just below it in the fourth quarter, although the total rainfall of the year was 45 per cent. below that of the preceding year. In 1874 the rainfall of the first and second quarters was below the mean line, of the third and fourth quarters above it, and the total rainfall of the year was about equal to that of 1873. In 1880, judging by the records of the second, third, and fourth quarters (that for the first quarter is wanting), the rainfall was much below the average, and in 1881, in which there was an excessive amount of rheumatic fever, the rainfall was defective in the first and fourth quarters of the year. The chief interest, however, centres about the year 1888, in which year the great epidemic of 1887-89 reached its climax. It will be noted that in the second quarter of each year the rainfall was much below the average from 1884-88 inclusive, in the third quarter at least from 1885-89, and in the fourth quarter from 1885-90. In the first quarter of 1885-86 and of 1888-89 rainfall was also deficient (1887 is missing). It is evident, therefore, that this great epidemic in Glasgow had been preceded by a deficiency of rainfall for four or five years.

THE INFLUENCE OF GROUND WATER.

We have now completed our attempt at the analysis of climate in its relation to rheumatic fever prevalence, excepting the conditions of soil. Geologically, as already stated, the data do not exist for a statistical statement as to the relative influence of different soils on this disease. Inasmuch, however, as the influence of soil upon health is probably determined chiefly by its temperature and degree of moisture, and as the temperature is determined by its porosity and the degree of moisture, we may be able where subsoil water observations are extant to ascertain if there is any relationship between it and the amount of rheumatic fever. The height and the degree of oscillation of the ground water are the two chief factors concerned. It is generally agreed, as stated by De Chaumont,* that "a persistently low ground water, say 15 ft. down or more, is healthy; that a persistently high ground water, less than 5 ft. from the surface, is unhealthy; and that a fluctuating level, especially if the changes are sudden and violent, is very unhealthy." According to Pettenkofer the most unhealthy time is during the fall of the ground water. Dr. Copeman* (p. 355) says: "It is well known that the disease [rheumatism] evinces a preference for open basins and plateaux exposed to the wind, for damp and deeply cleft valleys, and for sea coasts or the shores of great rivers. Dampness of soil may, however, predispose to the disease from the fact that it renders it cold, and this will be the more likely to be the case at low elevations and where there is an impermeable subsoil such as clay; but no sweeping assertion can be made on this point, as the necessary data for the institution of the comparative frequency of the disease on different kinds of soil are unfortunately wanting." This sentence fairly represents the present state of our knowledge on this subject, and brings out the association between dampness of soil and excess of rheumatism, which has become accepted as indubitable. That such an association is more than dubious we shall presently see. It may be further

added that there is probably no association between an impermeable clay subsoil and rheumatism such as is indicated above. All that follows tends to the conclusion that porous soils, being more subject to variations of humidity and temperature and containing a much larger proportion of ground air, are more prone than impervious soils to be the medium from which such telluric contagia as that of rheumatic fever are received. The greatest difficulty in investigating this problem has been the dearth of regular and long-continued ground water observations in this country. The records of the Lewes-road well at Brighton form an unbroken series of almost daily observations since 1867. From the curve of monthly maximum and minimum levels it will be seen that the minimum depth of water in the well was 50 per cent. higher in 1894 than in 1864. The water is pumped from the well almost daily, but owing to the opening of new wells in other parts of the watershed this well is not now worked more than formerly. The levels may, therefore, be fairly taken as representing the influence of seasonal and climatic factors practically undisturbed by variations in pumping.

1892	145	116

The years of highest level of ground water coincide with three out of the four years in which also the greatest range of ground water occurs. In these three years the amount of rheumatic fever was below the average. In the fourth year (1887) in which there was a great range of ground water, but at a much lower level, there was a severe epidemic of rheumatic fever culminating in 1888, in which year the range of ground water was much smaller. The range in 1887 was 68 ft. 9 in., as compared with an average range of 66 ft. 5 in. in the three other years of greatest range, 1873, 1877, and 1883; but the minimum depth of water in the well in 1887 was 1 ft., as compared with an average minimum for 1873-77-83 of 12 ft. 3 in. That a great range of ground water has no essential relationship with rheumatic fever is further shown by the years of smallest range. In four such years (1874-89-90-93) there was a great excess of rheumatic fever. In two other years of small range (1884-85) there was little or no excess of rheumatic fever. How do these two years compare with the preceding four as to level of ground water? The average of the minimum levels in 1874-89-90-93 was 8 ft. 7 in.; in 1884-85 it was 8 ft. 4 in.—practically no difference. It would appear, therefore, that smallness of range of ground water is not a necessary concomitant of excessive rheumatic fever, though the two usually coexist. Looking next at the question of simple level of ground water we find that the years of lowest level are associated with excessive rheumatic fever, and that the years of highest level are always associated with a small amount of rheumatic fever.

A general inspection of the curve of monthly levels of ground water shows a series of regularly and continuously high levels each year from 1867 to 1872, culminating in an exceptionally high level in the spring of 1873. Now the curve alters in character. In October-December, 1873, the rainfall was only 7.84 in. The total rainfall in 1873 was 25.42 in., as compared with 36.90 in. in 1872; and following on this condition of things in 1873, the ground water in 1874 failed to

* Stevenson and Murphy's Hygiene, vol. II., p. 324.
* Lectures on State Medicine, 1875.

show more than half the normal spring rise. The sum of the monthly maximum levels of the well for this year was 375 ft., as compared with 568 ft. in 1873. Corresponding to this fall in the level of the ground water came with rapid onset the epidemic of rheumatic fever in Brighton in 1874. The epidemic continued in 1875, when the ground water had risen considerably, though it was even now lower than in several preceding years. In 1876 the ground water had about the same level as in 1875, but the epidemic of rheumatic fever had ceased.

Between 1877 and 1880 occurred another fairly steady fall of ground water from a maximum at the beginning of 1877, and accompanying this there was (so far as can be judged from the imperfect records) a rise in the amount of rheumatic fever, reaching its maximum in 1880, when the spring rise in the level of the ground water almost failed as in 1874. As on the previous occasion, rheumatic fever then fell slowly in amount, reaching a minimum in 1884. In 1884 an exceptionally low level of ground water was again reached, but rheumatic fever was now also very low in amount. A study of the preceding table will prove that the anomaly cannot be explained on any difference between 1884 on the one hand and 1874 and 1880 on the other hand in regard to the amount of variation of the ground water level. It may be surmised that the time of year at which the tide of ground water turned has some influence. In 1874 the ground water was receding right on to December. In 1880 the following tide only began in November, while in 1884 the flow commenced in August. I have been unable to obtain any monthly statement of cases of rheumatic fever in 1884 with which to check my hypothesis. Whether we take the view that deficient rainfall is a condition directly favouring excess of rheumatic fever or only indirectly through the agency of a lowered ground water, the events of 1884 and the next three years are somewhat puzzling. In 1884-85 the rainfall and the aggregate level of the ground water were deficient in the first year, and still more deficient in the second year. Rheumatic fever was 34 per cent. below the average in 1884, and 12 per cent. below the average in 1885. In 1886 the rainfall had increased, so also had the height of the ground water, and so also had rheumatic fever (to 8 per cent. above the average). The chief rainfall of 1886 (13.61 in. out of a total of 33.25 in.) occurred in the fourth quarter. In the first quarter of 1887 5.06 in. of rain fell, but the total amount in 1887 was only 23.14 in., and the ground water therefore rapidly fell. The increase of rheumatic fever in 1887 was great, it being now 141 per cent. of the average amount. In 1888 no spring rise of ground water occurred, and the rheumatic fever in that year increased to 173 per cent. of the average, an amount greater than in any other year. In July, 1888, there were 4.26 in. of rainfall, and in November 4.81 in., and the total rainfall in 1888 was 28.16 in. Hence the spring rise of ground water reappeared in 1889, and with it the rheumatic fever declined to 129 per cent. of the average amount. In the years 1890 and 1891 the level of ground water was low, and in 1891 lower than in 1888; and yet if we take the acute rheumatism curve, as heretofore, its prevalence was at or below the average. A reference to the original documents, however, shows that while in 1889 the number of cases of acute rheumatism in the County Hospital was 39 and of subacute 2, in 1890 the numbers were 32 and 23, in 1891 they were 24 and 15, in 1892 they were 28 and 12, and in 1893 they were 41 and 3. It is evident, therefore, that there has been some transference, and that for this period the curve for acute and subacute rheumatism is the most trustworthy. Accepting this fact, it may be said that rheumatic fever in Brighton in 1890 and 1891 was much above the average. Looking at the whole period—August, 1887, to September, 1891—it is evident that the ground water was persistently low, and it is equally evident that rheumatic fever was during the same period generally excessive, with minor variations.

Mr. Baldwin Latham, C.E., who has made the subject of well levels a special study, has kindly furnished particulars of the maximum and minimum levels of the well water at Wickham Court, Kent, in the chalk three miles from Croydon. From 1866-72 the level did not vary very greatly. In this respect it greatly resembled the Brighton well, both being in the chalk. In 1873 a marked disturbance of the level of the well occurred, both maximum—in the fourth month—and minimum—the twelfth month—being higher than in the preceding years. In the same year an epidemic of rheumatic fever began, the admissions to the General Hospital for acute and subacute rheumatism being 16, as compared with 9, 10,

and 8 in 1870, 1871, and 1872 respectively. In 1874 they were 20, and in 1875 they were 27, but in 1876 they had again fallen to 14. In 1874 the maximum of the ground water for the year was in January, and was extremely low, and it evidently went steadily down, as the minimum level was recorded in December. So low a maximum level appears to me to indicate that the fall had already begun in the latter part of 1873, thus partially accounting for the fact that the commencement of the epidemic appeared to precede the fall in ground water level. I have been unable to obtain a monthly tracing of the ground water. In 1875 the ground water reached its very low highest level in April, and then fell to its minimum in December. In 1876 the water appears to have been rising until June, and reached a rather higher level than in April of the preceding year. The epidemic of rheumatic fever in this year greatly subsided; and in 1877, when the ground water had risen enormously even in January and attained its maximum in May, the epidemic had entirely disappeared. In 1878 occurred a small increase of rheumatic fever, with some fall in ground water level. In 1881 there is no similar correspondence between the two. In 1883 there is a repetition of what happened in 1873, there being a higher maximum ground water level than in 1882 with a considerable increase of rheumatic fever. The maximum of ground water in 1883 was, however, in April, and from that time there was a great fall to December. Between April, 1883, and April, 1884, a greater fall of ground water level occurred than at any previous time since 1873-84. The low level of ground water in 1884 does not appear to have been associated with an excess of rheumatic fever. The total number of rheumatic fever patients in 1884 was 11, as compared with 21 in 1883. It is noteworthy as bearing on this point that the total number of medical and surgical patients in 1884 was 208, as compared with 304 in 1883 and 339 in 1885. It is probable therefore that there were some special administrative causes at work in 1884, which prevented the rheumatic fever admissions to the hospital from being an accurate index of the total rheumatic fever in Croydon during that year. From 1885 onwards a disturbing influence comes into operation. The Croydon waterworks at Addington commenced work; and it has been recently stated in evidence before the Royal Commission on the Metropolitan Water-supply that the amount of water pumped out of the chalk is beyond the capacity of this water-bearing stratum. Although the curve for the Croydon well since that date shows some oscillations, they cannot therefore be regarded as natural in character. A fall of ground water occurred in 1885 and 1888, and in both these years there was some excess of rheumatic fever. In 1891 another fall occurred, greatest towards the end of the year, and this was accompanied by a slight increase of rheumatic fever in 1891-2.

I have now exhausted the English well levels so far as they relate to places in which corresponding information as to rheumatic fever is available. There is a great poverty of records in this most important field. Mr. M. A. Adams of Maidstone has since 1885 kept a very valuable record; but the hospital records for Maidstone are unfortunately too scanty to enable one to utilise his observations for rheumatic fever. Our next endeavour will be to collect such information as is available with respect to ground water in or about London in connexion with its annual prevalence of rheumatic fever. London, as will be seen from the geological map, lies chiefly on the London clay, which overlies to a great depth the chalk, the latter cropping out north and south of London, in Hertfordshire and Surrey. Over the clay is at parts a variable amount of gravel, and at certain points, as on Hampstead Heath, patches of Bagshot sands. Shallow wells in the gravel formed the chief source of water-supply to old London, and for some centuries the direction of the growth of London was determined by the possibility of obtaining such water. Hence districts like Kilburn and St. John's-wood, lying directly on clay, are necessarily of modern growth. There are no continuous records of levels of water in the surface gravel, though a few isolated observations are given in vol. ii. of Whitaker's "Geology of London." These are mostly notes of trial borings &c., and are not repeated.

In 1885 a valuable report⁷ on the Decrease of Water-supply was issued by a committee of the Royal Meteorological

⁷ Quarterly Journal of the Royal Meteorological Society, vol. xi, No. 55, July, 1885.

Society. So far as can be judged from the investigations of this committee 1859 and 1860, years of low and high water respectively, corresponded with a rather low death-rate from rheumatism. The high water in 1861 and in 1866 corresponded with a low death-rate, and the low water in 1864 and 1865 with a high death-rate, from rheumatism. Low water in 1871 corresponded with a death-rate just below the average and a rather high hospital case-rate for rheumatism; and in 1873, with high water, the amount of rheumatism had not varied greatly, though rather in the direction of increase than of decrease. In 1874 and 1875, and again in 1884, low water was associated with excessive rheumatic fever, while in 1877, 1879, 1881, and 1883 high ground water accompanied a small amount of rheumatic fever. The series confirms the rule that low ground water is more favourable to the prevalence of an excess of rheumatic fever than high ground water. There is not wanting collateral evidence on the same point which can be brought up to the present date. At Barley, near Royston, in Hertfordshire, is a deep chalk well, from which records from 1864 onwards are available.⁸ This may be taken as approximately indicating 'the variations in level of the ground water to the north of London. In 1864-65 the well was low for the whole of the year. Then from a maximum reached in April, 1867, the level fell until the end of 1868, the spring rise of 1868 being very small. There were corresponding maxima of rheumatism in London in 1864-65 and in 1868.

In 1869 the ground water rose, and rheumatism in London declined. Between the latter half of 1870 and the end of 1871 the ground water was lower than it had been since 1864-65, and with this there was a considerable increase of rheumatic fever, shown better by hospital cases than by the death returns. In 1873 the ground water was again high at Barley, and from then was very low throughout 1874 and 1875, rheumatic fever being at the same time exceptionally prevalent in London. The next minimum amount of rheumatic fever in London was reached in 1879, and in the same year the maximum level of the ground water was reached. In 1880-81 there was some increase of rheumatic fever in London with a slight lowering of ground water. In 1883 the ground water was very high, and rheumatic fever reached its next minimum. In 1884-85 the ground water was very low and rheumatic fever very high. The records for 1887-88 are unfortunately wanting.

The water levels of a chalk well at Cow Roast in Berkhamstead run practically parallel with those for the well at Barley and need not therefore be given in detail. Several points of difference between the curves of ground water at Barley and at Brighton and Croydon will be evident. 1. The low levels in 1870 and 1871 are unrepresented at the two latter places, whereas the 1874 and 1875 low levels are common to all. In 1870 there was an epidemic of rheumatic fever in London which did not occur in Brighton or Croydon; whereas the 1874-75 epidemic was common to all. 2. The 1884-85 low level was shared by Brighton and Barley; but as we have already seen there was, if the data are to be trusted, no epidemic of rheumatic fever in 1884 in Brighton, while there was some excess of rheumatic fever in London. Will the difference in the two curves explain this? At the Barley well in 1883 there was no autumn flow of water; but from that point a steady and almost uninterrupted drop progressed right to the end of 1885; while at Brighton in each year the normal ebb and flow occurred in both 1884 and 1885. It will now be seen why I lay stress on lowness of ground water as well as on deficiency of rainfall in connexion with an excessive prevalence of rheumatic fever. It is true that the level of the ground water is, in the absence of varying degrees of obstruction to its outflow, dependent chiefly on the rainfall; but it is possible that local circumstances of geology &c. may cause a dry year to have a different effect or an effect to a different degree in two districts. This will be evident from a comparison of the Hertfordshire and Greenwich rainfall with that of Brighton.⁹ Thus in 1868, although the Greenwich rainfall was 4 per cent. above the average, and the Herts rainfall only 1 per cent. below the average, the ground water at Barley was low, and rheumatic fever was epidemic in London. In 1871 there was a greater deficiency of rainfall in Brighton than at Greenwich and in Herts, and no epidemic occurred in Brighton, while there was an epidemic in London. This was evidently associated with the fact that in 1870 the deficiency of rainfall in Brighton was

not so great as near London, and consequently there was not the same fall in ground water in the following year. In 1884 the deficiency of rainfall was 12 per cent. at Brighton, as compared with 13 per cent. in Herts and 25 per cent. at Greenwich, so that in this instance one might have anticipated from the rainfall alone a greater epidemic in London than at Brighton, but not that the epidemic would be entirely absent from Brighton, as was apparently the case. The same general results are obtained when the rainfall is split up into that of summer and winter. It may safely be asserted that there is a closer correspondence between low ground water and excessive rheumatic fever than between deficient rainfall and excessive rheumatic fever, and that deficient rainfall probably only operates when it produces a decided effect on the level of the ground water. If deficient rainfall were directly operative in producing excessive rheumatic fever it might reasonably be expected to produce its effect in the course of a few weeks. If so the year 1893, which was distinguished by a remarkable and protracted drought, lasting in London from the tenth to the twenty-fourth week of the year, might be expected to show its effects in a very perceptible form. I have plotted out the weekly admissions to Guy's Hospital during each week of 1893 in comparison with the weekly rainfall. There was no excess of admissions in the first half of the year, the number up to March 25th being 25 March 26th to June 24th 24, from June 25th to Sept. 30th 42, and from Oct. 1st to Dec. 30th 39. It is evident that the drought was not followed by any great excess of cases until the autumn, there being no rapid increase of cases during the long-continued drought. The levels of the chalk wells at Barley and Berkhamstead cannot be regarded as exactly indicating the degree of dryness of the subsoil in London. In the absence of direct well observations some further indications may be obtained from records of the amount of water passing down the rivers Lea and Thames in each year. When the river is in flood the ground water is undoubtedly high, and the indications of river gaugings may be regarded as intermediate between rainfall and well observations, the river being fed both from surface drainage and from ground water. Felde's Weir is situated on the river Lea below Ware at the junction of the Lea and Stort. The minimum flow was in 1864 (in August of that year). The next minimum flow was in September, 1865, the years 1864 and 1865 being the driest known in the neighbourhood of London. In 1864-65 there was an epidemic of rheumatic fever which, measured by the death returns, was only exceeded in magnitude in 1874-75. The year 1874 showed an almost equally small flow of water over the weir, and in 1884 and 1887-88 and 1890 the flow was below the average. In each case deficient flow over Felde's Weir was associated with some excess of rheumatic fever in London.

Summarising the conclusions which may be legitimately drawn from the facts already stated, there is a close relationship between rainfall, level of ground water, and amount of rheumatic fever. In Brighton, in which we have been able to compare the three with some degree of accuracy, the rheumatic fever curve follows more closely the curve of ground water than that of rainfall. Thus in the years 1869-70-71 there was deficient rainfall, which did not markedly affect the level of the ground water, and no increase of rheumatic fever occurred. In 1888 the rainfall was above the average, but the well level was low owing to the defective rainfall of the preceding year, and there was an excess of rheumatic fever. Similarly in London the excessive rainfall in 1875 was not followed by an immediate and sudden fall in rheumatic fever prevalence, which may be explained on the supposition that it did not raise the ground water sufficiently high after the drought of 1874. It was not until after the steadily increasing rains of 1877-78-79 that rheumatic fever in London again reached its minimum. Similarly in 1884 there were deficient rainfall and high rheumatic fever, but the high rheumatic fever continued in 1885 notwithstanding an increased rainfall. It is evident that the effect of deficient rainfall is not produced immediately. It takes time to develop; and it is warrantable to assume that the influence of deficient rainfall is exerted as the result of its effect on the subsoil, this effect usually showing itself by a marked lowering of the ground water.

Low ground water must be regarded as leading to excessive rheumatic fever not by any essential causative relationship between the two. The low ground water is an indication of certain conditions of dryness and temperature of the subsoil which greatly favour the growth of the telluric contagium of

⁸ Appendix to Report of the Royal Commission on Metropolitan Water-supply, p. 641.

⁹ *Ibid.*, p. 667.

rheumatic fever. This being so, it is conceivable that low ground water, when through collateral circumstances it is unassociated with the required conditions of temperature &c., may not be accompanied by an increase of rheumatic fever, though conversely we never find a high ground water accompanying excessive rheumatic fever.

[Dr. Newsholme concluded by summarising certain foreign returns as to ground water, his information on the point as regards Berlin and Munich being particularly exhaustive.]

LECTURE IV.

Delivered on March 14th.

ARGUMENT AS TO THE INFECTIVE CHARACTER OF RHEUMATIC FEVER.

MR. PRESIDENT AND GENTLEMEN,—Having stepped aside to consider the influence of climate, season, weather, and ground water on the prevalence of rheumatic fever, we can now resume the argument in favour of the view that rheumatic fever is a specific febrile disease. We have seen that rheumatic fever shares its greater prevalence in winter and spring with several other specific febrile diseases, and that its marked association with deficient rainfall is shared by enteric fever, scarlet fever, erysipelas, &c. In the case of rheumatic fever there is reason to believe that deficient rainfall is provocative of an increased prevalence of the disease, only after the effects of this deficiency have been produced on the subsoil; and it is probable that the same relationship holds good for the other diseases just named.

We may next consider how far the clinical features of rheumatic fever and its analogy with recognised specific febrile diseases confirm the view that it partakes of the same nature.

1. *The mode of onset*, with shivering, general aching, &c., is strongly suggestive of the invasion of the system by micro-organisms. It resembles most closely, perhaps, the onset of influenza. *Sore-throat* is an initial symptom in a large proportion of cases. Dr. J. K. Fowler estimates the number of cases in which throat symptoms are present as not less than 80 per cent. The throat symptoms, as in scarlet fever, may be extremely slight, but they probably form an essential part of the disease. Mr. C. R. Straton of Wilton, Salisbury, has described pathognomonic greyish-yellow sores on the mucous membrane of the throat or nose, which may be followed by rheumatic fever or chorea or may have no sequel; but so far as I know no other observer has remarked these.

2. *The progress of the illness* is very like that of a specific febrile disease. The continuous fever, the frequent simultaneity of articular and visceral lesions, the occurrence of epistaxis, and the protracted curve of the temperature all indicate an infective disease; while the general aspect of the patient gives the same impression. The tendency to hyperpyrexia, as in scarlet fever, enteric fever, and puerperal septicæmia, forms another point of analogy. The occurrence of endocarditis is suggestive of microbic action. With the possible exception of chorea, all the diseases in which endocarditis is known to occur are infective in character. It is true that the fever has no such definite duration as in scarlet fever, enteric fever, pneumonia, &c.; but this is largely due to secondary serous inflammations. In the atypical character of its temperature curve rheumatic fever resembles erysipelas rather than typhus or enteric or scarlet fever.

3. *The tendency to relapse* is another feature characteristic of the disease. This by no means negatives the hypothesis of infectivity. Relapses are common in erysipelas. Relapsing pneumonia is described by Dr. Sturges; relapses of influenza and of enteric fever are common; recrudescences of diphtheria not infrequently occur within a few days of the first attack, or when the patient is about to be discharged from hospital. A similar phenomenon has occurred in my experience in a small percentage of scarlet fever cases; the patient, while desquamating from scarlet fever, has developed a second typical attack, beginning with sore-throat, scarlet rash, and elevated temperature, and followed by a second desquamation.

4. *The liability to second and later attacks*.—There is a regular scale of immunity among the diseases admittedly infective. Perhaps a second attack of small-pox is less common than of any other infectious disease, but it does occur. Third attacks of scarlet fever are known. Diphtheria appears to confer very slight immunity against subsequent attacks. Erysipelas predisposes to subsequent

attacks, and we have in this respect an additional point of analogy between erysipelas and rheumatic fever.

5. *The influence of the personal equation* varies greatly in different instances. An unvaccinated person definitely exposed to the infection of small-pox seldom escapes. It is difficult to believe that any persons receiving the anthrax bacillus into a scratch would escape; but there are families—of one of which I am a member—in which no cases of scarlet fever have occurred for at least three generations, notwithstanding repeated opportunities of infection at susceptible ages; and there are conversely families in which scarlet fever occurs with a frequency (and sometimes a malignancy) quite disproportionate to the opportunities of infection. The proclivity of certain families to diphtheria and to enteric fever is notorious, though their members are living under the most diverse conditions. Hay fever might be taken as the type of a local infective disease in which a special personal proclivity—described by some as an idiosyncrasy and by others (as Hirsch) as some anatomical peculiarity of the organism—is required for the production of the disease; while small-pox might be taken as the type of an infectious disease in which personal proclivity or immunity (apart from vaccination) has but little influence. Rheumatic fever, like erysipelas, comes much nearer to hay fever than to small-pox. It is almost certain that the number of persons receiving the streptococcus of erysipelas into abraded points is much greater than the number developing erysipelas thereafter, and it is almost certain that more persons receive the rheumatic infection than there are rheumatic fever attacks.

6. *The method of infection* in enteric fever and cholera is almost always *viâ* the alimentary canal; in scarlet fever and diphtheria the infection may enter by the alimentary canal or be implanted by inhalation directly on the throat. In erysipelas it is doubtful whether the infection is always received at the point of traumatism or whether, as in the case of acute periostitis,¹⁰ the micrococci have reached the specifically inflamed part *viâ* the blood circulation. In the majority of cases an abraded surface is the point of inoculation of erysipelas, and idiopathic erysipelas may be regarded as non-existent. In rheumatic fever it is probable that the specific infection enters the system at the tonsils or some other part of the naso-pharynx.

7. *The degree of infectiousness*.—Here again there is a scale of decreasing infectiousness from such diseases as small-pox and measles at one end of the scale, to enteric fever and cholera, which are only infectious by their intestinal discharges, and to erysipelas, which is only infectious to pre-disposed persons and probably only when an abraded surface exists. Rheumatic fever comes last in the series, the exact degree of its infectiousness being unknown. Assuming that rheumatic fever is due to the multiplication in the system of a specific micro-organism there can be no doubt that the chief seat of its multiplication is in the affected joints. Now infection is greater or less in proportion to the exposure of the affected parts. The exanthemata are typically infectious; enteric fever less so, though its specific discharges gain exit from the body. The rheumatic fever infection is deeply buried in the joints; we have little or no positive evidence that its micro-organisms ever escape by any of the emunctory organs. It may be that they pay for their hardihood in invading the system by securing a sepulture in its cells.

8. The fact that the joints are the seat of the trouble in rheumatic fever itself favours the infective theory. The "vessels of the synovia of the joints appear to have some special proclivity to form a nidus for the wandering germs of disease," as of gonorrhœa, pyæmia, and we may add rheumatic fever. Dr. Payne surmises that probably mechanical causes produce this determination of bacteria, as in gout they produce the determination of urate of soda.

So much for the clinical and analogical aspect of the case. Next as to the *therapeutics* of the disease. The specific power of salicin and salicylic acid to speedily terminate this disease forms one of the most remarkable conquests of modern medicine. It is comparable with the specific power of quinine in malaria and of salts of mercury and iodides in syphilis. Although the specific organism of syphilis has not been satisfactorily isolated, its existence is generally admitted; and the pathogenic importance of Laveran's

¹⁰ Mr. A. H. Tubby, M.B., in Guy's Hospital Reports, suggests that the skin is the main portal through which the staphylococci pyogenes aurei producing this disease enter the circulation. He found the sweat ducts in a case of acute periostitis more dilated than usual and crowded with micrococci.

protozoal organism appears to be fairly well established. We may, therefore, fairly argue on the grounds of analogy that rheumatic fever belongs to the group of specific febrile diseases.

It is not necessary to enter in great detail into the dubious evidence which *bacteriology* has hitherto supplied. Cornil and Babes have described two organisms, bacilli and micrococci, in this disease. Wilson¹¹ found in the pericarditis of one case and the pneumonia of another case of rheumatic fever micro-organisms which he was able to cultivate. In 1887 Dr. Mantle isolated bacteria from the synovial fluid and cultivated them.¹² Petrone in three cases of rheumatic fever found in the serum taken from the knee of a rheumatic fever patient organisms similar to those described by Klebs as present in rheumatic endocarditis.¹³ Dr. J. P. Popoff, house physician to the Marine Hospital in Nicoläev, stated in a preliminary note in 1887 that he had isolated the microbe of rheumatic fever, but nothing further has been heard of it.¹⁴ Birch-Hirschfeld, at the Wiesbaden Medical Congress in 1888, reported five cases of rheumatism in which he found staphylococci or streptococci in the joints and on the cardiac valves. Bouchard and Charrin state¹⁵ that they have frequently found the staphylococcus albus in the pure state in the articular fluids in sub-acute and chronic rheumatism. Triboulet¹⁶ obtained negative results during the life of the patient from the synovial fluid in a case of chorea and rheumatism; but post mortem obtained colonies of staphylococcus albus and aureus on gelatine from the pericardial fluid and from the blood of the heart and vena cava. Sahli,¹⁷ in a case of rheumatic fever complicated by pericarditis, double pleurisy, and recent endocarditis without any trace of suppuration, found in the joints, pericardium, and on the vegetations on the endocardium and in the blood a microbe like the staphylococcus aureus. Dr. C. Sacaze,¹⁸ Chef de Clinique Médicale à la Faculté de Montpellier, describes the case of a man admitted to hospital for rheumatic fever eight days after he had abraded his foot. Pus from the sore foot showed abundant staphylococci albi. Dr. Sacaze thinks the foot may have been the focus from which the system was inoculated. M. L. de Saint Germaine¹⁹ has produced joint effusion as the result of the intravenous injection of staphylococci of feeble virulence. He points out, moreover, that in blennorrhagic arthritis, admittedly due to infection, the synovial fluid is sterile and no germs are found in the blood; we need not, therefore, be surprised at the lack of success in examination of the blood and synovial fluid for germs in rheumatic fever. Professor E. Leyden,²⁰ in a communication dated December, 1894, says he has isolated a particular form of diplococcus in certain cases of rheumatism which presents the peculiarity of not growing on ordinary culture media like gelatine, but only on human blood serum. It is, he states, quite different from a staphylococcus in its mode of growth. It may, however, be stated in short that the evidence in favour of any one of the above-cited organisms being the *materies morbi* of rheumatic fever is incomplete and unsatisfactory. *Experimental evidence* is wanting. There has been, so far as I know, no case of inoculation of rheumatic fever in the human subject by the blood of a rheumatic patient, so that the link in the evidence which has been supplied for malaria is still wanting for rheumatic fever. It is somewhat doubtful whether *comparative pathology* will be able to assist in the investigation. Professor MacFadyen, of the Royal Veterinary College, Camden Town, informs me that "nearly all veterinary authors describe both acute and chronic rheumatism as now and again attacking the domesticated animals, and some (Friedberger and Fröhner) regard the disease as due to an infection. I do not know of any experimental evidence for or against this. My own opinion is that much of what has been described under the head of acute articular rheumatism in the lower animals ought to be classed as pyæmia or septicæmia. I have never in the lower animals seen a case clinically

identical with rheumatic fever of the human subject. I have seen many cases of acute arthritis with several joints simultaneously affected, but only in young animals, and always traceable to infection at the umbilicus and demonstrably caused by bacteria."

DIRECT EVIDENCE OF INFECTIVE CHARACTER.

The epidemics of rheumatic fever in the eighteenth century are too distant and too vaguely described to be regarded as authoritative. The more recent epidemics described in previous lectures furnish more exact evidence, and I venture to say that in view of the mass of evidence now collected it will be difficult to deny the infective character of rheumatic fever. Infection may be conveyed (a) directly from person to person, or (b) indirectly from infective discharges, which gain access to soil, water, or milk, or other foods, or become desiccated in inhabited rooms. If in the years in which rheumatic fever is excessively prevalent it is communicated from person to person it is remarkable that so few instances in which this has been apparently noticed are on record, though this does not necessarily negative the occurrence of infection. We have a possibly analogous case in phthisis, the infective character of which, although until recently it was not suspected by the majority of physicians, is now well recognised.

The most striking of the observations favouring the view that rheumatic fever is directly or indirectly infectious may now be quoted. Dr. Ch. Fieissinger²¹ states that in the village of Oyonnax there are about 500 houses. In a dozen dry and well-aerated houses in one street of this village 10 out of a total of 21 cases of rheumatic fever in recent years have occurred. Of these 10, 4 were in the same house and 2 in the same room. In the last instance there was a year's interval and members of different families were attacked. Edlefsen²² at Kiel found that 728 cases occurred in 492 houses, or 100 houses for 148 cases. He had—

2 cases in one house	100 times.
3 " " "	27 " "
4 " " "	5 " "
5 " " "	5 " "
6 " " "	1 time.
7 " " "	1 " "

Two cases in the same house were observed 21 times in the same year, and 7 times in the same month. Three cases in one house in one year were observed 6 times. In 1883 out of 140 cases there were forty-nine houses in which previous cases had occurred. Friedländer of Leipzig, in the discussion on Edlefsen's paper, stated that out of 357 cases he had two houses with 8 cases, one with 7 cases, one with 5 cases, eight with 4 cases, ten with 3 cases, and eight with 2 cases. In one large corner-house he saw 12 cases of rheumatic fever in the years 1872-74, of which 7 occurred in April, 1873. In two other houses in one street he had 18 cases, 11 in the years 1870-71, and 7 in 1870. Port has shown the predilection of certain garrisons in Bavaria to suffer to an exceptional extent from rheumatic fever, and certain barracks of the same garrison. In this country there are also a few recorded cases indicating that the infection of rheumatic fever may *cling about certain houses* in a manner which strikingly reminds one of the same characteristic in diphtheria. Dr. Mantle²³ describes multiple cases in the same house. He describes particularly the case of a girl whom he attended for erythema nodosum. During her convalescence the mother developed her first attack of rheumatic fever, and in another week the father, who had been nursing his wife, had rheumatic fever for the first time. Scarlet fever and erythema nodosum were prevalent at the time in neighbouring houses.

In our review of the epidemicity of rheumatic fever one of the most remarkable features was the indications which it furnished of the *gradual spread of the disease*. In London, in Yorkshire towns, in Norway, and possibly elsewhere there were clear indications that the entire susceptible population was not attacked at the same time, but that the infection progressed from place to place, apparently the more remote parts (as in Norway) suffering at a later period than the nearer parts. This might, as already indicated, be explained on the supposition that the disease is directly or indirectly infectious; or it may be that the necessary reaction of environment to the specific virus, always endemic in each district, occurs in different years in different localities, or that the susceptibility of populations varies at different times.

The first supposition makes the method of spread of rheumatic fever very analogous to that of diphtheria. This disease has for some years been slowly creeping over England. Unlike measles or influenza, the outbreaks of which owing to their rapid infectivity have an explosive character, diphtheria progresses with remarkable slowness. Some large centres of population have hitherto almost entirely escaped; while London and the towns and districts within easy touch of it have suffered severely. It takes several years to obtain full grip of a population, and it dies out slowly. Not only is infection from patient to patient required, but a large amount of infection must be present before the disease assumes epidemic proportions. It is more probable that the *materies morbi* of rheumatic fever is omnipresent, but requires certain favourable conditions of environment before it can assume sufficient malignancy to fit it for aggressive parasitic life. These conditions of environment are especially related to deficient rainfall and low ground water, and a certain temperature of the soil. This probably does not exhaust the environmental conditions favouring the spread of rheumatic fever, but of others we know little or nothing.

It will be seen that, on the whole, we incline to the view that rheumatic fever is caused by a saprophytic organism having a tendency to assume a parasitic life; that in most years only a small proportion of these organisms survive to the stage of parasitism, owing to the activity of their natural enemies in the struggle for existence; but that in dry years associated with low ground water and an optimum soil temperature the growth of these organisms is favoured more than that of countervailing organisms, and an abnormally large number of them are released into the atmosphere in a desiccated condition and become parasitic in persons whose vital processes do not enable them to resist the invasion. In the present state of our knowledge the gradual extension of the disease appears to be best explicable on the supposition that local geological and meteorological conditions cause the difference in time at which the reaction between special subsoil conditions and the vital activity of the rheumatic fever virus occurs.

Incubation period.—Our investigation into the origin of individual cases of rheumatic fever would be greatly facilitated by a knowledge of its exact period of incubation. Whether, like scarlet fever, it is only a few hours or may extend to months like hydrophobia or malaria is unknown. It is not unlikely that in this disease there may be a "latent parasitism," the organism already housed in the system waiting for its development until the personal factors to be next considered come into play.

The *chronic character* of some forms of rheumatism may be used as an argument against its infective character. It is not certain that chronic and acute rheumatism are the same disease; but if they are we have the analogous cases of chronic and recurrent forms of diphtheria and of the long-continued life in the individual of the malarial poison.

[Dr. Newsholme then briefly reviewed the element of idiosyncrasy in rheumatic fever, remarking that the degree of personal resistance was probably more important than either infection or environment in determining an attack.]

It is conceivable that the susceptibility to rheumatic fever of an entire population will become greater at intervals. We have already seen that some of the curves show a tendency to *alternation of greater and less epidemics*. Districts suffering severely in 1868 had the 1875 epidemic slightly, and districts having the 1875 epidemic badly escaped lightly in 1884 to have a severe outbreak in 1888. This is by no means generally the case, though it is frequently seen in the curves for large communities. It might be argued that most of the susceptible persons had rheumatic fever in the greater epidemic, and that this accounted for the smaller dimensions of its successor. There is, however, no evidence that one attack of rheumatic fever confers even temporary immunity against a second, and we must carefully distinguish between the comparative immunity of an entire community and that of an individual. The community is, however, made up of individuals, and it is highly probable that the apparent comparative immunity of a community is really a question of temporary comparative barrenness of the soil in which the *materies morbi* grows.

Metschnikoff has described an immunity of the population of Versailles against cholera, even when their drinking water contains the cholera vibrio.²⁴ He ascribes this immunity to

the absence of "favouring organisms" in the alimentary canals of the Versailles. On this hypothesis the absence or presence of rheumatic fever in a locality may be a question of the "microbial flora" of the mucous membranes of its inhabitants. Rather than accept the notion of complete immunity of an entire population in presence of cholera infection by means of inhibitory microbes in their intestines, it is easier to doubt the identity of the cholera vibrio found in the Seine water supplying Versailles, or in the alternative to deny the pathogenic relation of the comma vibrio to cholera.

There can be little doubt that the influence of *heredity* in relation to rheumatic fever has been much exaggerated owing to its common confusion with gout. There appears to be but a slender foundation for the notion that there exists what is called by Charcot an "articular disposition," a sort of parent stem from which issue two primary branches, gout and rheumatism, or what is called an "arthritic diathesis," from which, according to J. Hutchinson, develop gout under the influence of dietetic causes and rheumatism from exposure. Yet it appears impossible to treat of rheumatism without the use of the words "diathesis" or "disposition," notwithstanding Dr. Pye-Smith's eloquent *caecat* against their use.²⁵ He asks, How are we to define a rheumatic disposition? "If the disposition is not carried out it remains an unproved assertion." It matters little, however, whether we regard the members of a rheumatic family as inheriting a special *disposition* to the disease, or the members of a non-rheumatic family as inheriting a special *immunity* from it—either hypothesis would be tenable—the result is the same. If under certain conditions a person of one family will develop rheumatic fever, while under identical conditions a person of another family will not develop rheumatic fever—and this must, I think, be admitted—we must acknowledge a special personal factor which in certain cases favours, or at least fails to prevent, an attack of rheumatic fever.

Injury has an important influence in causing rheumatic fever. It may occur in the form of actual mechanical injury or be produced by former disease, as erysipelas, or be the result of fatigue or exposure to inclement weather.

The fact that rheumatic fever occurs in a predominantly large number of cases in dry, hot seasons does not exclude the operation of the conventional "chill." The influence of cold is a question, not only of actual temperature, but of variations of temperature, which in this country are greater in summer than in winter. Pasteur has shown how artificial refrigeration makes the hen subject to anthrax; Platania that it renders animals more receptive to the pneumococcus. It is not necessary further to pursue the *modus operandi* of cold, though it is not unlikely that it may be by affecting the tonsillar structures and deteriorating their functions, thus rendering them unable to resist the invasion of buccal microbes.

In connexion with chill we may mention the *lactic acid theory* of origin of rheumatic fever, associated more particularly with the names of Prout, Todd, and Richardson. It is still doubtful if lactic acid is excreted by the skin, and there is no positive evidence that there is an excess of lactic acid in the blood of rheumatic fever patients. Richardson's experimental results are somewhat dubious. The only positive evidence in favour of the lactic acid theory is Foster's observations on two diabetic patients²⁶ in whom the prolonged administration of lactic acid produced rheumatic fever. Dr. A. Harkin²⁷ has suggested that Foster's cases were gout, as the small joints were chiefly attacked. The association of gout and diabetes is furthermore common. It is not necessary to deny that lactic acid is developed excessively in rheumatic fever. We simply maintain that if this is so the agent concerned in its production is a micro-organism which is the essential cause of this disease.

Corporeal over-fatigue undoubtedly opens the gate to rheumatic fever. This is in accordance with what we know of other diseases. It is probable that protracted labour predisposes to puerperal fever, and the influence of forced marches on the origin of enteric fever and dysentery is well known. Charrin and Roger increased the susceptibility of rats to anthrax and to symptomatic anthrax (Rauschbrand) by making them run a treadmill several hours a day. Fatigue probably favours rheumatic fever by causing temporary

accumulation of effete matter and by causing nutritive modifications owing to the mechanical attrition. It is fairly certain that fatigue affects the localisation of rheumatic fever, and that this is the rational explanation for the exceptional frequency with which the knees and ankles are attacked. According to Lebert and Gerhardt more than two-thirds of the attacks of rheumatic fever begin in the lower extremities, the exceptions being among those who use their arms more than their legs. According to Kelsch,²³ from 80 to 85 per cent. of the cases begin in the legs, and next by preference the right arm.

There are certain facts which appear to point more definitely to the influence of traumatism in causing rheumatic fever. Many surgeons have had experience of an attack of rheumatic fever following attempts to reduce an old dislocation or to release old adhesions about a joint. M. Verneuil gave an account of several cases to the French Academy of Medicine.²⁹ In one case a woman aged twenty-five years was six months in hospital with an attack of rheumatic fever, which ended in a stiff ankle-joint. Two months later she returned to the hospital, and the actual cautery was applied. This was followed by an attack of rheumatic fever, beginning in the affected foot and spreading to other joints. In another case a girl aged eighteen years had a tooth extracted. On leaving the dentist she suffered from torticollis. This was followed by pain in the shoulder, and then a definite attack of rheumatic fever set in. In other cases the traumatism attending accouchement has appeared to be the starting point of rheumatic fever. Such cases as the preceding, indicating the possibility of traumatic infection, appear to increase the probability of a close affinity between rheumatic fever and erysipelas, on which we have already touched. It is impossible to say more than a few words as to the influence of race, diet, and occupation on rheumatic fever, as there is a dearth of trustworthy facts on these points.

As to race there is no evidence, so far as we know.

The same remarks applies almost equally to occupation. The only statistics which would settle this question would be those dealing with the total rheumatic fever patients in a given community, classified according to age and sex, in proportion to the total population of the same community. Such statistics would obviously be unobtainable except where, as in Norway, rheumatic fever is universally notified.

Diet possibly has some influence, though exact facts are wanting. With one clinical fact every practical physician is acquainted—viz., the frequency of relapses when animal food is given too early after an attack of rheumatic fever. There is, however, no evidence on a large scale that omnivorous or chiefly carnivorous races are more prone to rheumatic fever than vegetarians.

[Dr. Newsholme then discussed at length an important aspect of his exhaustive study of rheumatic fever—viz., the affinities of the disease. In his summary of the points of contact and contrast the lecturer compared rheumatic fever with chronic rheumatism, when he alluded to the confusion of ideas which by calling all sorts of arthritic and gouty conditions "rheumatism" had led to the idea that rheumatism was caused by damp; with muscular rheumatism; with chorea, stating that the statistics of St. George's Hospital showed a remarkable similarity in seasonal and annual curve between the two diseases; with epidemic cerebro-spinal meningitis; with epidemic pneumonia; with erysipelas, in connexion with which he pointed out at length the striking resemblance between the curves of rheumatism, erysipelas, and puerperal fever, and gave his grounds for believing that sepsis as a common cause did not wholly account for the similarity; and with scarlet fever, where the occurrence of scarlatinal rheumatism furnished an obvious point of contact. He continued:]

The conditions of soil producing rheumatic fever and malaria appear to be almost exactly opposed to each other. It would appear that a moist soil which has been previously saturated with water, associated with a soil temperature of about 65° F., is most favourable to the development of malaria. It is true that the conditions of soil under which malaria may develop appear to be somewhat discrepant. In the Campagna it prevailed in an uncultivated soil which was dry and free from stagnant water; and the same applies to some parts of the Deccan. As a rule, however, it occurs in

marshy ground which has become superficially dried, and is intensified by any obstruction to the outflow of the ground water. In rheumatic fever we have seen that the greatest amount of rheumatic fever usually corresponds with the year of, or immediately following the year of, smallest rainfall, in which the ground water is exceptionally low, and that the least rheumatic fever corresponds with the years in which there is the shallowest layer of dry earth between the ground water and the external atmosphere. The seasonal distribution of the two diseases is dissimilar. In temperate climates malaria has a maximum prevalence in spring and in autumn, and a minimum in winter, when rheumatic fever is most prevalent. In the most intensely malarious spots of the tropics the maximum prevalence of malaria is markedly associated with the rainy season; if the rainfall is not excessive the malaria usually reaches its maximum when the rain ceases. Alternations of drought and moisture with a moderately high temperature seem most favourable to malaria; whereas rheumatic fever is most abundant when the deficiency of rainfall has been exceptionally protracted and has produced a marked and exceptional drying of the subsoil.

We are now in a position to take a general survey of rheumatic fever and the diseases with which it is most closely allied. We have shown by evidence derived from death returns and hospital returns in various countries and from the notification returns in Scandinavia that at intervals of a few years rheumatic fever prevails epidemically, though in the intervals it is never entirely absent from any community from which we have been able to obtain returns. Some of these epidemics have been so widespread as to deserve the name of pandemics, among which we may specially mention those occurring in 1868, in 1874-75, and in 1884.

The epidemic prevalence of rheumatic fever has always occurred, so far as this country is concerned, in years of exceptional scarcity of rainfall. Judging by the evidence in this country, the deficient rainfall appears to produce this effect by causing an exceptionally dry and warm subsoil, which is usually associated with low ground water. In the instances where records were available it has been found that when deficient rainfall was, owing to its seasonal distribution, not accompanied or followed by exceptional lowness of ground water there was no epidemic prevalence of rheumatic fever. It is probable that mere lowness of ground water is not the only factor concerned in favouring rheumatic fever, but this along with some other hitherto unknown factor of temperature of soil or rate of flow of ground water. Whether this is correct or not, it is certain that dryness of soil is favourable to the occurrence of rheumatic fever to an epidemic extent.

We have some difficulty in placing rheumatic fever in its exactly appropriate place among the specific febrile diseases, though of its claim to a place among them there can be no doubt. Is it an infectious disease like whooping-cough or measles? If so, it has hitherto succeeded admirably in concealing its true character. Direct infection if it occurs is exceptional. Is it a purely miasmatic disease like ague? We have already given reasons for regarding the poison of ague as absolutely distinct from that of rheumatic fever. They may both, however, be miasmatic diseases in the sense that the virus is formed in the soil and is not transmissible directly from patient to patient. Or it may be miasmatic-contagious like enteric fever or cholera, one phase of its existence being passed saprophytically in the soil and the next in the human organism. Whichever of these latter hypotheses is correct, we have no doubt that it is essentially a soil disease. It is impossible in the present state of our knowledge to be certain whether rheumatic fever is due to an organism which is usually solely saprophytic and only becomes parasitic when its habits of life are altered by the stimulating effects of dryness and warmth of soil, or, to put it in another way, only migrates into parasitic life when extra-corporeal food is deficient; and whether this organism after its rapid multiplication in the system is eliminated therefrom and subsequently infects the soil, or whether each case of the disease involves a fresh infection from contaminated soil, we cannot at present state. There are many points of analogy with tetanus and erysipelas, more particularly the latter. The virus of tetanus inhabits the soil, and can only become parasitic when directly inoculated. It is highly probable that the same is true for erysipelas; it may also be true for rheumatic fever.

PROPHYLAXIS.

A disease like rheumatic fever, which certainly occurs chiefly in dry soils, appears to afford but little scope for preventive measures. It would appear at first sight to strike at the root of the hygienic axiom that a dry soil is the most healthy. It is probable that a distinction must be carefully drawn between dryness of soil due to its drainage, to the removal of locks, mill-ponds, &c. from the neighbouring streams, and dryness of soil due to a series of hot and dry seasons. The latter would be associated with a higher temperature of the soil than the former, and would undoubtedly have a different effect on the biological quality of the soil.³⁰

A CASE OF SARCOMA OF THE BRAIN SUCCESSFULLY REMOVED BY OPERATION.

By GEORGE R. MURRAY, M.A., M.B. CAMB.,
M.R.C.P. LOND.,

HEALTH PROFESSOR OF COMPARATIVE PATHOLOGY IN THE UNIVERSITY
OF DURHAM; PATHOLOGIST TO THE HOSPITAL FOR SICK
CHILDREN, NEWCASTLE-ON-TYNE;

AND

W. G. RICHARDSON, M.B. DURH., F.R.C.S. ENG.,
SURGICAL REGISTRAR, ROYAL INFIRMARY, NEWCASTLE-ON-TYNE.

The following case is published as an example of the good results which may be obtained by the removal of a cerebral tumour, even when it has attained a considerable size.

The patient was a married man aged thirty-six years. Before the commencement of the present illness he had always enjoyed good health, and was well able to do hard work. He had never had any severe illness or injury, nor could any history of syphilis be obtained. Soon after the beginning of February, 1894, and as far as can now be ascertained on the 11th of that month, he was suddenly seized with a slight attack of Jacksonian epilepsy. He stated that in this attack the left elbow was raised from the side, and that the forearm was pronated and supinated in the flexed position several times in rapid succession. The attack was limited to the left arm, and he was perfectly conscious all the time. Nine days later, on Feb. 20th, he had a similar attack, again involving the left arm only, but accompanied by a tingling sensation, which was felt all over the left side of the head. Four days after this he had a third attack similar in all respects to the second. Since then he had had no general or localised convulsion. He did not notice any loss of power in the left arm immediately after these attacks. He continued at his work for another week, till one day he felt cold and was seized with nausea, which was followed by a severe attack of vomiting. The next day (March 4th) he found that he had lost some power in the left arm, and since then he had been unable to work. The left arm gradually became weaker till it finally was almost completely paralysed. About a fortnight after he left his work he felt that he was beginning to lose power in the left leg, but there had not been any convulsive seizure involving the leg. Attacks of vomiting occurred regularly two or three times a week. About the beginning of April he began to complain of an aching pain in the right temporal region. The symptoms all gradually became more marked up till the middle of May, when Dr. Murray first saw the patient in consultation with Dr. H. S. Baumgartner of Newcastle and Mr. Yoakley of Heaton. At that time the patient complained of headache on the right side and severe attacks of vomiting. There was paralysis of the left arm, with considerable loss of power in the left leg, so that he could only get about the house with difficulty by the help of a stick. There was well-marked double optic neuritis, the neuritis being rather more advanced in the right eye than in the left. The symptoms pointed clearly to the presence of a cerebral tumour, which we concluded primarily involved the cortex of the middle third of the ascending frontal and ascending parietal convolutions, and was extending upwards towards the longitudinal fissure. It was determined to administer full doses of potassium iodide for a few weeks in the first place, and, if no improvement took place, to have the tumour removed. Fifteen grains of potassium iodide were given three times a day.

Beyond a temporary diminution in the frequency of the attacks of vomiting no improvement took place, and the condition of the patient became worse, so that at the end of six weeks we decided that the tumour should be removed without any further delay.

Condition of the patient at the time of operation.—The patient complained of headache which was always confined to the right side of the head. The pain, however, appeared to shift from one part of this side of the head to another, and was sometimes felt in the temporal and at others in the occipital region. He also complained of feeling as if he had received a blow on the head in the right parietal region. He frequently heard noises in the head, which at one time sounded like an engine at work and at another like a bell ringing. He had severe and prolonged attacks of vomiting almost every other day. The speech was clear and the memory unimpaired. His temper had become irritable, but in all other respects his mental condition was unaffected. On tapping the right side of the head there was found to be a small tender area surrounding a point situated one inch from the middle line on a line drawn at right angles to it and passing down through the right external auditory meatus. The eyes were examined by Dr. Archibald Percival, who reported their condition to be as follows. Vision was nearly $\frac{1}{2}$ with either eye. The fields were normal. In each eye the colour sense was good and the colour field normal. Light sense was impaired slightly. There was pronounced optic neuritis in both eyes. Left disc: $\frac{1}{2}$ mm. swelling. There was a small amount of hæmorrhage near the lower and outer margin of the disc. The vessels were partly obscured by the œdema in places. Right disc: the swelling was estimated at 1 mm.; a few fine vitreous opacities were occasionally and with difficulty seen. The tension was the same in both eyes. Elevation and depression were good. Conjugate movements were rather jerky, ranging to the extreme right or the extreme left. The pupils acted, but not very briskly, to light and accommodation. The other cranial nerves were unaffected. The left arm was almost completely paralysed, as the patient was unable to raise the arm by means of the shoulder muscles, and the movement which he made in endeavouring to raise the arm was due to rotation of the scapula. In the sitting position, with the arm hanging down, he was unable to execute the slightest movement of the forearm, hand, or fingers. When he was lying on his back in bed with the arm at his side he was found to have still some slight power in the flexors and extensors of the elbow-joint. There was a slight amount of rigidity of the biceps and supinator longus muscles. There was scarcely any diminution in the size of the muscles of the left arm and forearm. The thenar and hypothenar eminences were rather soft and flattened owing to some wasting of the intrinsic muscles of the hand; the interosseous spaces were more conspicuous than on the right. The triceps, the supinator longus, and the other muscles of the forearm were in a marked condition of myotatic irritability, and responded actively to mechanical stimulation. The patient could just walk across the room without support, but as a rule used a stick or supported himself by the furniture. The left leg dragged considerably as he walked; when sitting he could cross the left leg over the right knee. The power of flexion and extension of the left thigh was much less than on the right side. The extensor muscles of the left knee-joint were also less powerful than on the right, but the flexors were much weaker. He was unable to execute any movement of the foot or toes. Sensation to touch, pain, heat, and cold was unaffected. The muscular sense was lost for the left arm, as he was unable to tell the position of the limb unless he was aided by visual or sensory impulses. The knee-jerk was much exaggerated on the left; it was also more active than usual on the right. Ankle-clonus could be obtained on the left side, but not on the right. The superficial plantar reflex was exaggerated on the left. On pricking the dorsum of the left foot a reflex flexion of the foot took place, but only after an unusually long interval. The limbs of the right side were unaffected. Micturition and defæcation were carried out normally, and in all other respects the patient was healthy.

In this case the presence of headache, vomiting, and double optic neuritis associated with unilateral paralysis clearly indicated that the diagnosis of a cerebral tumour was correct. The localised epileptic attacks affecting the left arm, followed by progressive loss of power of that arm, and later by loss of power in the left leg, showed that the tumour was situated in the right half of the brain, and that it primarily involved either the cortical motor centre for the

³⁰ We regret that exigencies of space have compelled us to omit paragraphs here and there of Dr. Newsholme's interesting lectures, but though the points of disconnexion are here and there apparent the argument has not, we trust, suffered.—ED. L.

arm or the fibres passing down from that centre in the internal capsule. As localised convulsion of the left arm was the first symptom of the tumour which appeared, we concluded that the tumour primarily involved the cortex. As the facial muscles were unaffected it appeared most probable that the tumour had first of all involved the middle third of the right ascending frontal and ascending parietal convolutions, and had subsequently extended upwards and inwards towards the longitudinal fissure, affecting either the cortical leg centre or the fibres passing down from it, but to a less extent. We agreed, therefore, that it would be advisable to expose the surface of the brain at a point corresponding to the junction of the upper and middle thirds of the fissure of Rolando.

Operation by Mr. RICHARDSON.—Two days before the operation the head was shaved and washed with soft soap and then with turpentine. The day before the head was treated in the same way. In the forenoon the right side of the head was marked out with an aniline blue pencil with Reid's lines. A mark was made at the junction of the upper and middle thirds of the line corresponding to the fissure of Rolando. This point was exactly on the part of the scalp which was tender to per-

exposed surface were seen to be brain, but the major part was tumour, which was easily distinguished from the adjacent brain substance by its uniform bluish tint. The opening in the skull was then enlarged, chiefly forwards and upwards, by cutting away the bone with punch forceps, the dura mater was divided until the whole surface of the tumour was exposed surrounded by brain except at the upper part where the tumour was attached to the dura mater. The exposed area of the tumour was about the size of a penny (the part which was seen is indicated as a circular patch in the engraving of the upper surface of the tumour). It was readily separable from the surrounding brain by a director, but it was then found that about half an inch from the surface the growth expanded in all directions. As the upper part of the tumour was attached to the dura mater this point was untouched until the body of the growth had been cleared. By enlarging the opening in the bone, by incising the dura mater when necessary, and by carefully working with a flat periosteal elevator, the tumour was lifted out of the brain and then only remained attached to the dura mater. It was not found necessary to damage the brain in any way. By working with the elevator on the denser new growth

cussion with the finger tip. In the evening the whole head was again washed with soft soap and then with turpentine, after which a dressing of lint soaked in a 1 in 1000 solution of corrosive sublimate was applied over the whole scalp and was left on until the time of operating. The operation was performed on July 1st, 1894, at 11 A.M. Immediately before the administration of chloroform a quarter of a grain of morphia was injected hypodermically. A horseshoe incision was made from a point two inches behind and above the right ear to a point two inches behind and above the external angular process of the right orbit, the convexity of the incision reaching to the sagittal suture. The scalp and periosteum were raised in one sheet, the vessels being caught in clip forceps. A one-inch trephine was applied at the point overlying the junction of the upper and middle thirds of the fissure of Rolando, and a crown of bone was removed. The same trephine was again applied a little above and in front of this hole and another crown was removed. The two trephine circles overlapped, forming one opening. On removing the crowns of bone the pulsations of the brain were observed. The dura mater was incised along the posterior and lower margins of the opening about a quarter of an inch from the edge of bone. On raising the dura mater the cranial contents bulged up and the lower and back parts of the

the elastic tumour came out of its bed and through a comparatively small aperture in the surface of the brain. The cavity in which it had lain slowly closed as the tumour was removed. There was not much bleeding from the cavity, and what there was very soon ceased. One cortical vein was ligatured. The tumour was then taken away along with the dura mater, and in separating the latter a vein was cut across close to its point of entry into the longitudinal sinus. This vein was caught in clip forceps and ligatured with catgut. The shallow cavity now left was filled with corrosive sublimate gauze, the tail of which was brought out at the posterior part of the scalp wound. The scalp was sutured with silk and a dressing of corrosive sublimate gauze and wood-wool was applied. The operation lasted about an hour. The patient was returned to bed considerably collapsed, the pulse feeble, extremities cold, and general sweating. At 3 P.M. he was still unconscious. Respiration was 14 per minute; the pulse 100 per minute. The pupils were very small; conjunctival reflex returned. The extremities were warm. The patient moved his head. At 6 P.M. the patient regained consciousness and felt comfortable. He vomited once or twice.

Except from the diploe there was very little bleeding. From the diploe more than a pint of blood was lost, and this

was much the most serious contingency. During the operation the brain was not handled, all the manipulations being on the tumour, the flat surface of the periosteal elevator alone coming in contact with the brain. The instruments and sponges were kept in a 1 in 40 carbolic lotion. There was very little sponging, and all things were kept as dry as possible. There was never any free lotion in the wound. The dura mater having been removed on account of its attachment to the tumour, the pieces of bone were not replaced; a permanent opening is thus left in the skull, measuring two inches and three-quarters by two inches and a quarter.

Description of the tumour.—The appearance presented by the tumour is well shown in the two plates, which represent the actual size of the growth. It measured 3 in. in length, 2 in. in breadth, and 1½ in. in depth. On microscopical examination the tumour proved to be a sarcoma.

After-progress.—The progress of the patient after operation was in every way most satisfactory. The temperature only once reached 100° forty-eight hours after the operation; on four other occasions only did it rise above 99°. After the first forty-eight hours the pulse ranged between 72 and 88. As an immediate result of the operation the vomiting and the noises in the head ceased, the pain in the head was relieved, and the irritability of temper disappeared. With the exception of the night after the operation, when sleep was broken, the patient slept about eight hours each night. For the first twelve days the wound was dressed daily on account of the large amount of cerebro-spinal fluid which saturated the dressings. On the third day the gauze plug was removed. This was not accompanied by any hæmorrhage, but a small fusiform piece of brain substance, one inch in length and a quarter of an inch in diameter, came away with it. On the fourth day the entire scalp and face were very much swollen and cedematous, especially on the left side, on which the patient had been lying. This swelling, which continued during the fifth day and gradually subsided on the sixth without having produced any ill-effects, appeared to be entirely due to extravasation of cerebro-spinal fluid into the subcutaneous tissues. The wound united by first intention with the exception of the small opening, through which the cerebro-spinal fluid continued to leak for about three weeks. There was profuse diuresis during the whole of the third week. For five days six pints of urine were passed in the twenty-four hours. On the sixth and seventh days of the third week nine and a half pints of urine were passed. The urine was clear and did not contain either sugar or albumen. The muscles of the left arm and leg rapidly regained power in the following order. On July 3rd there was already some increase in the power of the extensors and flexors of the forearm. The patient could extend and invert the left foot and flex the great toe to a very slight extent. On waking on the morning of the 7th the patient stretched himself, and the nurse noticed that he stretched out the left arm as well as the right, and also extended the fingers of the left hand, movements which he was quite unable to execute voluntarily while fully awake. On the 9th the power of flexion and inversion of the left foot and of flexion of the great toe had increased. The associated movements of the left arm occurred each morning when the patient stretched on waking. On the 12th he got out of bed and walked across the room. In doing so he was able to carry the left leg forward more strongly than before the operation. On the 17th the patient could abduct and raise the left arm a little. In the erect position he could fully flex the elbow, and the rigidity of the biceps had diminished. There was a distinct increase in power in both the flexors and extensors of the hip-joint and of the knee-joint. When lying on his back he could flex and invert his foot and flex the toes to a slight extent. In walking the left foot was no longer dragged, but was carried forward with a semicircular sweep, and when planted showed a tendency to assume a position of slight equino-varus, with the toes spread out. The reflexes had not changed in character since the operation. On the 20th the fingers were voluntarily flexed for the first time. On the 28th there was considerable power of flexion in the left thumb and index finger. He could walk about the house without any support. On the 30th the thumb and all the fingers of the left hand could be feebly extended. On Aug. 1st the left wrist could be slightly extended. On the 10th the wrist and fingers could be fully flexed and extended and a stick could be grasped in the left hand. The optic neuritis had very much diminished since the removal of the tumour. On the 13th the hand could be pronated and supinated. On Sept. 3rd

all the muscles of the left upper limb could be made to contract voluntarily and all movements executed, though much less strongly than on the right. He could walk two miles with the help of a stick. On Oct. 10th the patient felt well. There was no headache, pain, or noise in the head. He slept and ate well, and his general health was excellent. He could walk as many as five miles with the help of a stick. He could use the left arm for many purposes. He could touch the back of his head, take off his cap, and use a fork with the left hand. There was, however, some rigidity of the muscles of the arm. The muscular sense was still deficient, but not to such an extent as it was three months before. He still walked with a limp, but could advance the left foot fairly well, and there was less circumduction than there had been. The reflexes remained just as they were before the operation. Only slight traces of the optic neuritis could now be seen. There was slight bulging of the scalp over the site of the tumour, but now that the hair had grown again this showed but little.

Remarks.—The improvement which had taken place in the condition of the patient within three months of the removal of the tumour was very considerable. From being unable to lift the arm or walk further than across the room, the patient could use the arm for many purposes and walk five miles without fatigue. The headache, vomiting, and noises in the head were removed at once by the operation. The optic neuritis steadily subsided after it. The after-progress was as straightforward as it usually is after quite a minor operation. The treatment was carried out in an ordinary bedroom, and, except at the operation itself, without the aid of skilled nursing. The improvement has been fully maintained, and the patient is now (March 5th, 1895) in excellent general health. He says that he can walk "any distance." The grasp of the hand is as strong on the left as on the right side.

Newcastle-on-Tyne.

CASE OF A GIRL SAID TO HAVE BEEN MIRACULOUSLY CURED OF PARALYSIS AT ST. WINEFRIDE'S WELL, NORTH WALES.

By THOMAS OLIVER, M.D. GLASG., F.R.C.P. LOND.,
PHYSICIAN TO THE ROYAL INFIRMARY, NEWCASTLE-UPON-TYNE.

THE publicity given in the daily and weekly press to the "miraculous cures" that have been effected at Holywell, the pictorial representations of St. Winefride's Well in several of the illustrated papers, and the fact that for several weeks past I have been the recipient of letters of inquiry from various parts of England, most of them hitherto unanswered, must be my excuse for placing in THE LANCET the medical facts of a case already encircled by the halo of romance and round which is being thrown an air of mystery. For some time past Holywell has been the resort of an increasing number of invalids, each hoping by immersion to be suddenly relieved of his or her infirmity. If the stories of the "miraculous cures" thereof accomplished can be accredited the Well of St. Winefride bids fair to rival Lourdes, whose grotto is now world-known, and of which and the hordes of human wrecks that besiege it Zola has given us a marvellously realistic delineation. Holywell claims its cures not less truly though less pretentiously than the little French town that nestles in the Pyrenees; and, as one of the recent cures that have taken place at Holywell concerns a patient who was formerly under my care in the Newcastle Infirmary, I shall briefly state the history of her case before her visit to the Well of St. Winefride and since her return from it, simply introducing here and there relevant facts that have been supplied to me by the patient or the mother, who accompanied her to North Wales.

The patient, a young woman aged seventeen years, was admitted to the Royal Infirmary, Newcastle-upon-Tyne, on April 28th, 1894, complaining of curvature of the spine, pain in the legs and of difficulty in walking, pains in the head, and occasional dimness of sight. Her father died fifteen years ago from typhoid fever; her mother is still living and healthy. She has five brothers and one sister, all of whom are rather delicate. At the age of eleven patient left school, but owing to ill-health did nothing until

she was fourteen years of age, when she entered domestic service, leaving it a year afterwards on account of sore-throat. She began to menstruate at the age of sixteen and has been regular. The patient stated that her spine had been bent as long as she could remember, and that she has always walked with her head fixed and thrown a little forward. During June, 1893, she had left-sided pleurisy without effusion, and was in bed for a month with it. On recovering she noticed that she walked more bent than formerly, and that she had pain in the head and neck; but it was not until eight months after this that the pain affected her legs and knees. The pain is described as having been constant and more of an aching character, aggravated by walking or if the limbs were touched. Her condition on admission was as follows. **Alimentary system:** the lips were normal and the teeth fairly good; the tongue was large, pale, and coated with white fur. She had some dysphagia owing to enlarged tonsils. The palate was highly arched, which caused the patient to speak rather indistinctly. Her appetite was poor and the bowels were constipated. **Circulatory system:** the pulse was 84 and feeble; the heart sounds were normal; the lungs were healthy; the pupils were fully dilated and equal; they reacted to light and accommodation. **Nervous system:** there was slight angular curvature of the spine, most pronounced in the dorsal region. There was marked hyperæsthesia on touching the skin over the spine, and on percussing it pain was felt particularly in the lower dorsal region. On pressing the head down towards the spine pain was felt in the cervical region. On pricking the sole of the left foot with a pin no pain was experienced at all, but there was hyperæsthesia of the right sole. Sensation was normal in the front of both legs. Ankle clonus was present. The knee-jerk was normal on engaging the patient's attention. On asking her to walk it was noticed that the head was thrown forward and that she somewhat dragged the left foot. On May 5th, 1894, the borders of the optic disc were even and the retina was healthy. There were still analgesia of the left foot and excessive knee-jerk in both legs. As the case was regarded as neurotic or one of a functional character in a girl the subject of a slightly curved spine of old standing and unaccompanied by any symptoms of increasing cord pressure, it was not considered necessary to retain her as an in-patient in the infirmary. Here it may be stated that prior to coming under my care the patient had been treated by one of my surgical colleagues, who regarded the case as one of hysterical spine.

I saw nothing more of the girl until, receiving several letters in regard to her "miraculous cure" at Holywell, I wrote to the mother asking that her daughter might be brought to me at the infirmary for examination. This was done on Feb. 7th of this year, and the following statement was supplied to me by the mother. In November, 1894, her daughter was lying in bed a perfect cripple. She was quite unable to stand. She had not been out of bed for seven months, hence the fact of her not appearing at my out-patient department at the infirmary. Mr. Galbraith of Gosforth had attended her from time to time. Owing to information of a friend in the county of Durham "having been miraculously cured of lameness at Holywell," it was arranged that the patient in question should visit the sacred well. Accordingly, in the early morning of Nov. 27th she was dressed, lifted from bed, and taken by a cab to the railway station, placed in the recumbent position in a third-class railway carriage, and conveyed to North Wales, reaching Holywell station in the evening of the same day. Thence she was carried by the porters to an omnibus and thus driven to the hospice, a distance of one mile and a half. The hospice is stated to be a receiving home for Roman Catholic patients visiting Holywell, and is superintended by two nuns. It is not, however, confined exclusively to Roman Catholics. Protestants are equally admitted, provided they give some indications of their faith in the virtues of the water. The patient was one of several inmates, male and female, and at ten o'clock on the morning following her arrival at the hospice she was wheeled to St. Winefride's Well, where she was stripped. She put on a bathing dress and was carried by her mother and another woman who was staying at the hospice into the well. Shortly after her immersion the patient is stated to have fainted, but in spite of this she was retained in the water. There was no religious service going on at the wellside, nor had there been any special service that morning at the hospice before leaving—nothing but the ordinary service, which, however, the patient had not attended. The patient, I may remark, is a Roman

Catholic. It appears that after the immersion no immediate effect was noticed. She was therefore wheeled back to the hospice and placed in a chair in the general ward. After sitting in a bent position for an hour the mother states that her daughter sat upright, and maintained this position more or less all that day, but made no attempt to walk. Next morning at the same hour the patient was wheeled to St. Winefride's Well and again immersed. After a few moments she is said to have moved both legs, and to have raised herself up the steps out of the well. She subsequently walked back to the hospice—a distance of about half a mile—supported between her mother and another woman. On the day succeeding this the patient walked to the well in company with, and supported by, the same two friends, and was again immersed. When in the water she is credited with having said, "Mother, what a queer sensation; there is a burning heat in my back." To which the mother responded, "Oh, Hannah, pray, you are going to be cured." The patient immediately afterwards walked out of the well to the dressing-room, where "steam was noticed rising from her body," and a feeling of tingling and heat complained of in her spine, and the mother on examining the back uttered, "Oh, Hannah, your bones have gone in." She walked back to the hospice, where she was examined by a medical man, who pronounced her a marvellous cure. That evening she walked to the town and for the next three days strolled about. Exactly one week after their admission the patient and her mother left the hospice, the daughter sitting bolt upright in the omnibus. To the surprise of the porters at Holywell station she walked into the train. She reached home on the evening of Dec. 4th, walking at the end of her long journey from the tramway terminus to Corlodge, a distance of nearly a mile. Her condition on Feb. 7th, 1895, was as follows. There was still slight inclination of the head to the right, causing an apparent shortening of the right side of the neck. There was also slight lateral curvature of the spine in the dorsal region, the inclination being to the right, with distinct prominence of the two lower dorsal spines. No pain was complained of on percussing the spine. On bending it was noticed that the column moved *en masse*, with a tendency for the body to be deflected to the left. There was slight hyperæsthesia of the skin of the back, the prick of a pin and the application of the blunt point of a pencil being evidently followed by exaggerated impressions. The knee-jerks were excessive; there was slight ankle clonus. The patient walked remarkably well and was evidently proud of being able to do so. There was no halting or dragging of the limbs. When walking it was noticed that her head was thrown forwards and with a distinct inclination to the right side. She still wore a poroplastic jacket which was supplied to her in the early part of 1894, and on the recommendation of the medical practitioner who saw her at Holywell was going to wear it all the winter. Her heart and lungs were healthy. Menstruation was regular.

These, then, are briefly the medical facts of the case. A girl who was recognised by myself in April, 1894, as a neurotic, with slight spinal curvature but without evidence of increasing pressure on the cord, and by one of my colleagues at the infirmary as suffering from hysterical spine, subsequently developed paralysis of the lower extremities, which lasted for six months. There is no need to doubt the paralysis any more than there is to question her present ability to walk. The patient left home in November for Holywell strongly buoyed up with hope and with great expectations in regard to her recovery, having received the Holy Communion in bed on the day before starting. The charge at the hospice is 7s. a week for each inmate. This, with the railway and other incidental expenses, made it absolutely necessary, as the family belonged to the labouring classes, that the visit to North Wales should not be unduly prolonged. It is difficult to appraise at its proper value the effects of immersion of the whole body in an exposed well of cold water in the early morning of a November day upon one unaccustomed to such a proceeding, but at any rate they must be considerable. What want of will caused and what strength of will failed to accomplish in our patient strong physical and mental impressions overcame. It is not the first time that cold water suddenly applied to the external surface—over a large area and nearer home than Holywell—has roused up dormant nerve energies and been followed by results as satisfactory and permanent as the cure of the patient in question "miraculously" accomplished by dipping in the Well of St. Winefride.

Newcastle-upon-Tyne.

TROPHIC INTESTINAL AFFECTIONS IN THE INSANE.

By THOMAS PHILIP COWEN, M.D., B.S. LOND.,
ISTANT MEDICAL OFFICER, COUNTY ASYLUM, PRESTWICH, MANCHESTER

FROM time to time cases of diarrhoea arise in insane people which are not due to any specific cause. This "simple" diarrhoea usually occurs in one or other of what Kraft-Ebing¹ calls the "organic psychoses," and in general paralytics for the most part. It is of comparatively long duration, and is very often fatal. The necropsy reveals an enteritis or a colitis, which is often ulcerative, or both combined. The causes of these intestinal affections are not at all evident. None of the ordinary causes are present. The clinical and pathological accounts are in all strikingly similar, and it is most probable that all these cases have a similar origin. There are two varieties of this simple diarrhoea, although the more serious one is probably only an advanced stage of the milder variety, and not a distinct type. 1. A very watery alvine flux, very frequently repeated, without passage of blood or excess of mucus; usually without any pyrexia or marked general symptoms. This may be fatal, but is often recovered from. Obvious intestinal lesions are rarely observed. 2. A frequent diarrhoea, with vomiting, pain, often tenesmus, and with marked constitutional symptoms. The stools often contain blood, excess of mucus, and slime occasionally. This affection is usually fatal. The necropsy shows an inflammatory affection of the ileum or colon, and often marked ulceration of the mucous membrane. We have had under our care in the asylum at Prestwich, Manchester, a fair number of such cases. During the last three years thirty-two cases have thus arisen which have proved fatal. (See table below.) It will be seen from this table that the greater proportion occur in males and in those suffering from general paralysis of the insane. The remainder occur in either stuporous melancholia or in dementia of an incurable type. Most of the cases occurring are of the second variety.

Clinical history.—Twenty-two cases are in males and ten in females. The age varies from twenty-six to sixty-eight years, but most of the patients are over forty. The duration of the illness varies from three days to as many months. The onset may be sudden or gradual, the mode of onset varying with the acuteness of the attack. The symptoms vary somewhat with the situation and extent of the lesions. Diarrhoea is usually the earliest and most striking symptom. Vomiting occurs at times, but not invariably so, being often absent. Abdominal pain is a very variable quantity, some appearing to suffer pain, but this is not common. The demented condition of most of the patients of course renders them less susceptible to, and less apt to complain of, pain. Distension of the abdomen occurs but rarely. The stools are generally loose, small in quantity, but frequently passed. Tenesmus is at times present, especially when the lower bowel is affected. Blood is often found in the motions and often unmixed. Slime, shreds of tissue, or even sloughs are at rare intervals seen. The stools have a very offensive smell usually. There is excess of mucus at times. Perforation with resulting peritonitis is rather rare. Pyrexia is moderate, irregularly manifested, and often absent. A fatal result is the rule, but a few do undoubtedly recover, although presenting serious symptoms.

The amount and extent of the congestion of the mucous membrane are very variable. It usually affects both the small and the large intestine, but is more general in the ileum. The patches are small and discrete as a rule, but they may coalesce, forming largish areas of congestion. The colour varies from the bright red of inflammation to the dull red of

passive congestion. If the congestion become extreme there is a tendency for submucous hæmorrhages to occur. One form of ulcer is probably produced by the abrasion of the already damaged mucous membrane superficial to one of these hæmorrhages. The solitary follicles are very often enlarged. This condition is usually found in the colon, although by no means uncommon in the small intestine. Peyer's patches are rarely affected. The follicles are swollen and softened, and there is a tendency to their disintegration forming small rounded ulcers and leaving patches of healthy mucous membrane. This follicular ulceration of the intestine is fairly common, seven cases of the thirty-two showing this condition markedly. In two cases perforation had occurred (Nos. 3 and 12); in both the ulceration was confined to the ileum. The ulcers had extended in depth, forming punched-out conical cavities through the peritoneum forming the floor, of which an opening had formed with resulting peritonitis. In the colon the follicular ulcers, while remaining of small size, showed much variety in their depth, and often extended down to the peritoneal coat of the bowel. This was well seen in Case 8. Follicular ulceration is, we think, essentially different to the next form—ulcerative enteritis and colitis. This ulcerative process is more common than the follicular one, and is *sui generis* apparently. The ileum and lower part of the jejunum in the small, and the ascending and transverse colon in the large, intestine are the parts affected usually, but no part is exempt. The mucous membrane of those parts is congested, swollen, and softened. Here and there, in a mild case, are irregular ulcerations, often with yellow adherent sloughs in parts. The ulcers are of various shapes and sizes, and in a severe case tend to run together so as to form an irregular network of ulceration, leaving islets of sodden and congested mucous membrane in their meshes. The bases of the ulcers are but little thickened. The floor may be formed by submucous tissue, by muscular fibre, or by the sub-peritoneal tissue. Perforation may occur, but in our experience is not common. The solitary follicles may be swollen, are rarely ulcerated, and not seldom are normal in appearance where they can be distinguished. Peyer's glands are commonly unaffected or but slightly swollen. The mesenteric glands are at times enlarged and softened. The acute inflammatory affection of the intestine present the usual appearances of acute enteritis or colitis. The inflammation is often intense and quite localised, but without any local causation within or without the bowel. An intense phlegmonous enteritis may even thus arise without any evident cause. In the case described in association with a dorsal myelitis, the inflammation of the upper part of the rectum was most intense, the inner coats having sloughed out. In a few cases evidences of diseased bloodvessels were found (atheroma), but whether this had any part in the degenerative process is doubtful. Microscopically, the usual signs of inflammation were present, but nothing specific was made out. The organisms present were those usually found in the intestine, but the bacillus coli communis was especially common. An inoculation of some of the contents of the gut on nutrient media often yielded an almost pure culture of this organism. In all these cases there was a total absence of any specific disease. In fact, we have excluded all cases in the records in which there was the least suspicion of tubercle, typhoid fever, dysentery, Bright's disease, or syphilis.

These are the facts. How can they be explained? Writers on medicine describe, but as a rarity, a simple ulcerative enteritis or colitis. Fagge² says: "Apart from typhoid fever and tubercle the small intestines are very little liable to serious primary diseases, and the jejunum particularly is remarkably exempt." Hale White³ describes a most interesting series of twenty-nine cases of "simple ulcerative colitis and other rare intestinal ulcers." He, however, throws no light on their origin, which he says is extremely obscure. In asylum practice these simple ulcerations and inflammations are by no means infrequent, and this is shown by the fact that in our practice during the last three years at the Prestwich Asylum, Manchester, thirty-two such simple uncomplicated cases have been examined after death. We venture, therefore, to put forward the proposition that these intestinal lesions form a part of the general degenerative process, and that they owe their origin to a nervous perversion. The only term that expresses this perverted nervous action is the rather vague one of a trophic or a dystrophic affection. The

¹ Fagge's Medicine, third edition.

² Guy's Hospital Reports, 1883.

³ Lehrbuch der Psychiatrie, fourth edition, page 325.

reasons for such an opinion are: (1) the rarity of such lesions in the sane; (2) the comparative frequency in the degenerate insane; (3) negative evidence as to causation; (4) their association with other trophic lesions; and (5) the association of such lesions with disease of the central nervous system.

The mental and nervous affections associated with these lesions are, as has been shown, of a markedly depressive or degenerative nature. It is not at all unusual in the degenerate insane, and more especially in general paralysis of the insane, for trophic lesions to occur—e.g., atrophies of skin, muscles, and bones; acute sloughings of tissues, as seen in acute bedsores and herpetic and bullous eruptions in the so-called "insane abscesses"; a peculiar low form of pneumonia, which is probably of nervous origin; and acute cystitis of so-called trophic origin. Some of these lesions occur in the same patients in whom the intestinal affections arise later. In fact, one or other of these tropho-neuroses is always present. In one man trophic ulcers of the legs were present (Case 4). Dr. Hale White⁴ describes a case of "intense colitis" associated with disease of the central nervous system (double descending lateral sclerosis). Dr. Acland⁵ "raises the question whether in diseases of the spinal cord we may not get an ulceration of the intestine comparable to other trophic lesions, such as acute bedsores. He records two cases of disease of the spinal cord, in both of which small ulcers are found in various parts of the bowel." Curiously enough, a short time ago a similar case arose in this asylum. A localised phlegmonous inflammation of the large intestine occurred in association with a transverse myelitis in the dorsal region. (See notes.) In this case there was no local cause for the affection of the gut, and the only explanation valid was that the lesion was a trophic one.

We may thus explain the causation of the two varieties of "diarrhoea" first described: 1. The watery alvine flux frequently seen in general paralytics is due apparently to centric irritation of the vagus nerve. Buzzard⁶ regards a similar condition met with in certain cases of tabes as dependent upon irritation of the vagal nucleus in the medulla. "In these cases the flux is probably the result of paralysis of the splanchnics—the vaso-motor nerves of the intestines—and to the resulting transudation of fluid from the blood-vessels into the bowel, with the accompanying increased peristalsis."⁷ This vaso-motor paralysis gives rise probably to the varying patchy congestions and hæmorrhages. 2. The ulcers found are very often of the round, punched out appearance which is usually held to be of dystrophic origin, and seen *par excellence* in the gastric ulcer.⁸ The other variety of ulceration, as best seen in the ulcerative colitis, is probably due to the same influence—i.e., to a further extension of irritation of the nuclei in the medulla, causing a trophic inflammation and ulceration of the intestine. The ulceration once started is probably extended by the influence of the intestinal microbes on tissues of lowered vitality and powers of resistance. The bacillus coli communis is most potent for evil in this respect. Subjoined is a summary of the fatal cases with fuller reports of nine of the most typical cases. In conclusion, the tropho-neurotic origin of these intestinal affections seems to us the only possible explanation of their occurrence in the present state of our knowledge. Little notice seems to have been taken up to now of these neuropathic lesions, and there are but few and scanty references to them in the journals and text-books. We think, therefore, that some description of these very interesting cases should be published, so that they may be more generally recognised and investigated. We wish to thank Mr. H. R. Ley, the medical superintendent, for his kind permission to use the notes of the cases.

Phlegmonous inflammation of the large intestine, associated with myelitis of the dorsal cord.—A man aged thirty-four years was admitted in 1886 suffering from acute mania. He never improved, but became after a while feeble-minded with a few fixed delusions. His bodily health remained good until March, 1892. He was then found to be suffering from a gradually increasing weakness of the legs. This weakness rapidly increased until he became almost completely paraplegic (both of sensation and of motion). The knee-jerks were absent. There were retention of urine and incontinence of feces. He complained of girdle pains at the level of the

ninth dorsal vertebra. Early in April, 1892, he began to suffer from vomiting, abdominal pain, and diarrhoea. There was no rise of temperature. The stools contained blood, but the blood was not mixed with the feces. On April 20th he passed a cast of the intestine two inches long, which was evidently the mucous membrane and part of the muscular wall of the gut. Examination per rectum was negative. The diarrhoea persisted, but at intervals only. Later he developed cystitis with irregular rises of temperature. He had a small bed sore. He died from exhaustion on May 18th, 1892. The necropsy showed a transverse myelitis at the level of the eighth and ninth vertebrae, with a spinal meningitis also localised. There were thickening and roughening of the vertebrae at this level, but no definite tuberculous lesion existed. There were evidences of old tubercle at the left apex (of lung). Cystitis and pyelitis with commencing abscesses in the kidneys were present. There was an intense proctitis, but of limited extent, affecting the middle part of the rectum. The inner coats had sloughed away, leaving a rough, shreddy surface. No evidences of any local origin of this rectal affection were found. The rest of the bowel appeared to be fairly healthy. The intestines were moderately distended.

Trophic Intestinal Affections in the Insane.

No.	Sex.	Age.	Mental disorder.	Intestinal lesion.
1	M.	68	Senile mania.	Patches of congestion throughout entire tract.
2	M.	44	General paralysis.	Patchy congestion; solitary follicles of colon enlarged.
*3	M.	50	Do.	Follicular ulceration of ileum; perforation.
4	M.	37	Chronic mania.	Patchy congestion of colon with superficial ulceration.
*5	M.	34	General paralysis.	Patchy congestion of ileum and colon with submucous hæmorrhages.
*6	M.	57	Do.	Ulcerative colitis; follicles enlarged.
*7	M.	55	Do.	Enteritis.
*8	M.	47	Do.	Follicular ulceration of the colon.
9	M.	34	Do.	Patchy congestion of ileum; follicles enlarged.
10	M.	26	Epileptic dementia.	Follicular ulceration of colon.
11	M.	43	General paralysis.	Ulcerative colitis; submucous hæmorrhages.
12	M.	68	Chronic melancholia.	Punched-out round ulcer in ileum, which had perforated; ulcerative colitis.
13	M.	43	General paralysis.	Patchy congestion of ileum and colon.
14	M.	43	Do.	Patchy congestion of ileum; ulcerative colitis.
15	M.	51	Chronic mania and dementia.	Patchy congestion of ileum; ulcerative colitis (superficial and deep rounded ulcers).
16	M.	48	General paralysis.	Patchy congestion and superficial ulceration of ileum.
17	M.	63	Secondary dementia.	Ulcerative enteritis and colitis; follicles enlarged.
18	M.	33	General paralysis.	Ulcerative enteritis; follicles enlarged.
19	M.	40	Do.	Ulcerative enteritis; congestion of colon.
20	M.	50	Do.	Patchy congestion of colon; enlarged follicles.
21	M.	49	Do.	Follicular ulceration of colon; congestion of ileum.
*22	M.	54	Melancholia attonita.	Ulcerative enteritis and colitis.
23	F.	34	Do.	Subacute enteritis; submucous hæmorrhage.
24	F.	29	Do.	Follicular enteritis.
*25	F.	28	General paralysis.	Ulcerative colitis.
*26	F.	35	Do.	Patchy congestion of ileum; ulcerative colitis.
27	F.	28	Do.	Patchy congestion of ileum and colon.
28	F.	50	Acute melancholia with stupor.	Enteritis and colitis; enlarged follicles.
29	F.	46	Chronic melancholia.	Inflammation of ileum and ascending colon.
30	F.	38	Epileptic dementia.	Patchy congestion; superficial ulceration of ileum.
31	F.	40	Secondary dementia.	Ulcerative enteritis and colitis.
32	F.	50	Chronic melancholia.	Ulcerative colitis.

* The cases marked (*) are described more fully.

CASE 3. *Follicular ulceration of ileum in a general paralytic.*—A man aged fifty years was admitted on April 11th,

⁴ Ibid.

⁵ Transactions of the Pathological Society of London, 1885.

⁶ Diseases of the Nervous System.

⁷ Bevan Lewis: Text-book of Mental Diseases.

⁸ Cf. Dr. W. M. Ord, St. Thomas's Hospital Reports, 1892.

1892. He was in the second stage of general paralysis. He had already become demented, but still retained his old exalted delusions. His muscular power was feeble and his muscles were shrunken. His skin was greasy and shiny. He was wet in his habits. On May 5th he was found to have slight right hemiplegia, which passed off in a few days. On July 8th he complained of abdominal pain and tenderness about the umbilical region. He vomited several times and was evidently very ill. There was slight looseness of the bowels. Previously there had been constipation for a few days. The temperature was normal. The stools were dark coloured, but did not contain blood. On July 9th the vomiting and abdominal pain continued. There was dullness on percussion in the left iliac fossa. There was marked tenderness of the abdomen which was slightly tympanitic. The stools were liquid, but did not contain blood or slime. The temperature was subnormal. There was evidently peritonitis. On the 10th he died, collapsed, early in the morning. The necropsy showed marked congestion of the mucous membrane of the last four feet of the ileum. The solitary follicles were enlarged and in a few ulceration had begun. Six rounded punched-out ulcers were found in the above area and in two cases perforation had occurred with resulting peritonitis. There were no other lesions found anywhere, and no tubercle or other specific disease.

CASE 5. *Patchy congestion of ileum and colon with submucous hemorrhages in a general paralytic.*—A man aged thirty-four years was admitted on March 19th, 1892, suffering from general paralysis of the insane in its second stage. He presented the usual physical signs of that disease. Mentally, he was demented, irritable, and childish. He rapidly got worse and was bedridden in the course of the next six months. At times he suffered from looseness of the bowels, which alternated with constipation. Towards the end the diarrhoea became more marked. The motions were yellow, liquid, but never contained blood. Signs of hypostatic pneumonia developed during the last week. On Sept. 7th he died from exhaustion. The necropsy showed marked patchy congestion of the ileum and colon, with submucous hemorrhages. The solitary follicles were not enlarged. There was no ulceration of the intestine or sign of tubercle. The lungs showed hypostatic congestion of the bases.

CASE 6. *Ulcerative colitis with general paralysis of the insane.*—A man aged fifty-seven years was admitted on Oct. 25th, 1892, suffering from general paralysis of the insane with exaltation. The case was a typical one in onset and course. The only symptom of intestinal trouble was the occurrence of rather severe diarrhoea, from which he suffered off and on during the last month of his life. The stools were watery, pale yellow, and did not contain blood or mucus. There was no vomiting. No pyrexia was present. Treatment was of no avail. He died exhausted about three months after admission. The necropsy showed the usual changes in the nervous system found in general paralysis. There was slight hypostatic pneumonia of both lungs and marked atheroma of the arteries. There was commencing granular change in the kidneys. The mucous membrane of the descending colon and sigmoid flexure showed several very congested and inflamed patches. Towards the centres of these patches, which were of limited extent, the surface of the mucous membrane was abraded, leaving small shallow ulcers. The solitary follicles were enlarged, but none showed any ulceration. There was some thickening of the wall of the gut opposite to these patches. The bowel was not distended. The small intestine appeared to be normal.

CASE 7. *Catarrhal enteritis in a general paralytic.*—A man aged fifty-five years was admitted on Oct. 31st, 1892, suffering from general paralysis of the insane with melancholia. He had marked delusions of obstruction of the bowels, and was at one time very suicidal. About a week before his death he began to suffer from diarrhoea. He did not complain of pain, but there was some tenderness over the lower part of the abdomen. No vomiting occurred. There was moderate pyrexia, the temperature rising and falling irregularly, but not rising higher than 102° F. He died rather suddenly in a sort of faint. The stools were loose, yellow, and contained much mucus, but not blood. At the necropsy patchy congestion of the lower part of the ileum and cæcum was found. The congested surfaces were rough and granular, but showed no definite ulceration. The solitary follicles were not affected.

CASE 8. *Follicular ulceration of the colon in a general paralytic.*—A man aged forty-seven years was admitted on Dec. 8th, 1892, suffering from general paralysis of the insane with delusions of exaltation. He presented the usual

symptoms of that disease, which ran its usual course, until the onset of intestinal troubles. He began to have diarrhoea on March 7th, 1893, with vomiting and pyrexia. The temperature rose to 103.6° F. There was some pain in the abdomen, which was at first "board-like," without tenderness. The stools were yellow, liquid, and very offensive. During the next week the pyrexia continued, the temperature varying from 99° in the morning to 102° in the evening. The diarrhoea continued, the bowels acting very frequently. There was no marked tenesmus. The stools were yellow, almost like "pea-soup," and at times contained shreds of tissue and blood. There was also occasional vomiting. The abdomen towards the last became distended and tympanitic. There was some tenderness over the left side of the abdomen. Treatment was of no avail. He died from exhaustion on March 12th, 1893. The necropsy showed extensive changes in the large intestine, the whole of the colon and part of its sigmoid flexure being affected. There was much congestion of the mucous membrane in patches. The solitary follicles were greatly swollen, and many of them presented punched-out ulcers. In some the ulcerative process had only just begun, but in others the ulcers had nearly extended to the peritoneal surface of the bowel. None had actually perforated. The mucous membrane between these ulcers was darkly congested and superficially abraded. The wall of the bowel was distinctly thickened. The small intestine appeared to be normal. The brain showed the marked changes found in general paralysis. There were marked atheroma of the large vessels and considerable emphysema of the lungs.

CASE 22. *Ulcerative enteritis and colitis in a case of melancholia with stupor.*—A man aged fifty-four years was admitted on Dec. 11th, 1893, and died on Sept. 11th, 1894. He was tall, stout, but unhealthy-looking. He suffered from melancholia attonita. He used to sit in one position for hours, seeming quite crushed down by an overpowering weight of woe. He remained in the same dull, stuporous condition during the remainder of his life. He often had to be fed with the stomach tube. On Sept. 4th, 1894, there was slight pyrexia. Diarrhoea set in, with some abdominal pain. There was no vomiting. The stools were loose, yellow, and did not contain blood, slime, or mucus. On Sept. 5th the temperature in the morning was 100° F. and in the evening 100.6°. He passed frequent loose motions in small quantities. The abdomen was rather retracted. He did not complain, but this was probably due to his stuporous state. On Sept. 6th he was much the same. The tongue was dry, brown, and cracked. There was moderate pyrexia. The diarrhoea continued. On Sept. 8th streaks of blood and shreds of tissue were noticed in the stools. The looseness of the bowels continued. He was weaker. There were no fresh physical signs. The patient's condition steadily grew worse. The abdominal symptoms were persistent. The diarrhoea was as before. Death occurred on Sept. 11th from exhaustion. The necropsy showed marked ulcerations of the lower part of the ileum, and almost the whole length of the colon. The mucous membranes of the ileum and the colon were darkly congested, swollen, and superficially ulcerated. The solitary follicles were somewhat enlarged, but not ulcerated. Peyer's patches were unaffected. The ulceration of the ascending and transverse colon was most extensive, leaving here and there isolated patches of swollen but otherwise normal mucous membrane. The edges of the ulcers were sinuous, cleanly cut, and in the floor muscular fibres were exposed; none had, however, perforated. The other organs were healthy. The liquid faeces in the intestine were yellow, blood-stained, and most offensive. A growth was obtained from the intestine on agar-agar and on potato, which consisted of an almost pure culture of bacillus coli communis.

CASE 25. *Ulcerative colitis in a general paralytic.*—A woman aged twenty-eight years was admitted on July 7th, 1893, suffering from general paralysis with melancholic symptoms. She fancied that she had committed some dreadful crime and was eternally damned. There were typical physical signs of general paralysis. Her bodily health was fair. On Aug. 16th, 1893, vomiting and diarrhoea occurred for the first time. There was pain in the abdomen without tenderness or distension. The stools were loose, offensive, and contained a little blood. These symptoms persisted until the death of the patient, which occurred from exhaustion on Aug. 24th, 1893. There was slight pyrexia on the last two days. At the necropsy all the organs were found to be healthy except the colon. The brain presented the usual changes due to general paralysis. There was marked congestion of the cæcum and the ascending colon, with several

superficial ulcers of irregular shape, but rounded for the most part. The solitary follicles were not markedly enlarged.

CASE 26. *Ulcerative colitis with general paralysis of the insane.*—A woman aged thirty-five years was admitted on June 13th, 1893. She suffered from general paralysis with melancholia. She also had delusions of great sins committed and of eternal perdition. On Oct. 22nd, 1893 she began to suffer from diarrhoea, which persisted for two months. There was no vomiting, and pain was rarely complained of. There was no abdominal distension. The temperature at times rose to 100° F. The stools were loose, frequent, and contained at times blood, but never slime or shreds of tissue. Death occurred from exhaustion on Dec. 20th, 1893. The necropsy showed patches of congestion in the lower part of the ileum, and a rather chronic colitis. The mucous membrane of the colon was softened, thickened, and superficially ulcerated. The bases of the ulcers were thickened, and the floor was ragged and uneven, and stained a dark yellow by adherent faeces.

THE TRANSFER OF FEVER CONVALESCENTS, AND ITS EFFECT UPON THE OCCUR- RENCE OF ALBUMINURIA.

BY JAMES DICKINSON, M.B. LOND.,
MEDICAL SUPERINTENDENT, GORE FARM FEVER HOSPITAL, DARENTH, KENT.

DURING the year 1894, 1219 scarlet fever convalescents were transferred by road ambulance from the London hospitals of the Metropolitan Asylums Board to the Gore Farm Fever Hospital at Darenth. The patients were transferred at various stages of the disease, from the seventeenth day after admission onwards, and in all weathers and seasons. The object of this paper is to show what effect the transfer had upon the occurrence of albuminuria amongst those transferred.

Albuminuria, systematically examined for, was observed in thirty-nine patients within the first twenty-four hours of their arrival at the Gore Farm Fever Hospital. A trace of albumen is here excluded from consideration, unless proved by subsequent observations to have had clinical significance. The albuminuria observed in the thirty-nine patients referred to was for the most part considerable in amount—e.g., one-sixth to one-half albumen—and in at least six cases was accompanied by more or less hæmaturia, the more representing porter-coloured, the less smoky urine. Inquiry as to the previous history of these patients elicited the fact that five of them were under treatment for albuminuria at the time of transfer. These five will not again be referred to. The remaining thirty-four cases were either known or presumed to be free from albuminuria at the time of transfer. In nine of them an intermittent trace had previously been observed, but in none of them the considerable degree of albuminuria found after transfer to Gore Farm Fever Hospital. It is probable, therefore, that the transfer determined the onset of albuminuria in 34 out of 1219 patients transferred (2.78 per cent.), though it is possible that in some of these the albuminuria was not of fresh onset, but of greatly increased degree. The clinical course of the cases was remarkable, and may be illustrated by reference to the case of a male aged eight years. He was presumed to have no albuminuria at the time of his transfer. The urine passed during the night after his arrival at Gore Farm Fever Hospital was heavily laden with albumen, and gave blood reaction. During the next three days a trace only was observed. The urine then became entirely free, and remained free from albumen during the several weeks this patient continued under observation. While the case may be taken as typical, in some the trace of albumen persisted much longer than three days, and in four cases it persisted throughout the patients' stay in hospital. The rest were, at the time of their discharge, in perfect health and quite free from albuminuria. Thus the features which the 34 cases had in common were—(1) absence, or presumable absence, of albuminuria at the time of transfer; (2) a large amount of albuminuria immediately after transfer; (3) rapid subsequent disappearance or great diminution of the albuminuria. These striking facts would seem to establish

fully the connexion between the transfer and the albuminuria. Assuming this connexion to be established, some points of interest arise which may be referred to. 1. Out of the total number of patients dealt with during the year 128 were transferred, in three weeks or less from the dates of their admission, to the acute hospitals; they include 6 albuminuric cases, an incidence of 4.6 per cent. upon such cases. 735 patients were transferred after a stay in the acute hospitals of four weeks or more; they include 22 of the albuminuric cases, an incidence of 2.9 upon such patients. The chance occurrence of a case or two so appreciably alters the percentage that comparisons cannot fairly be based upon such small figures. Were any inference justifiable it would support the natural conclusion that early transfer involves a greater risk of precipitating albuminuria. 2. The incidence of the attacks did not appear to increase with the mileage traversed. Thus 653 patients were removed a distance of about fifteen miles, the incidence upon these patients being 3.51 per cent.; 394 patients were removed a distance of about eighteen miles, the incidence upon these being 3.04 per cent.; 172 patients were removed a distance of about twenty-two miles, the incidence upon these being 0.58 per cent. It must again be pointed out that when split up into several groups the number of cases becomes too small to form a safe basis for statistical inferences. It may be that a few miles more or less are immaterial. If any inference is to be based upon the figures it is that the occurrence of the attacks depends not upon the distance traversed but upon the attendant circumstances of the transfer. 3. With regard to the nature of these albuminuric attacks, I have no doubt that they would be rightly called nephritis. From the results it would appear that they are a form of nephritis which is of less serious consequence than that which attacks a scarlet fever convalescent who has never left the shelter of the sick-room. This fact is, after all, only an example of a clinical truth, namely, that organs which become inflamed from some definite external cause show more reparative power than those which develop inflammation independently of apparent external cause.

NOTES ON PULSE-RATE AND BODY TEMPERATURE.¹

BY WILLIAM CECIL BOSANQUET, M.A.,
FELLOW OF NEW COLLEGE, OXFORD.

THESE few notes on the above subjects are taken from a series of observations made on myself during a period of three years, extending from June, 1891, to June, 1894, and may possess some interest owing to the fairly long period of time over which they extend, even though the results do not present any striking novelty, but merely confirm in the main the accepted statements on these subjects. These observations on both pulse and temperature were taken—regularly as circumstances allowed—four times a day—viz., after breakfast, after lunch, before dinner, and at bedtime—corresponding in the main to about the hours of 9 A.M., 2, 7, and 10 P.M. The figures thus obtained weekly for each time of day were reduced to an average, and these averages to a general weekly average. Finally, an average for the whole year at each time was struck, and these last were taken together for the three years. This calculation gave the following results: temperature in the rectum at 9 A.M. 98.7° F.; at 2 P.M. 98.9°; at 7 P.M. and at 10 P.M. 98.8°—showing on the whole a scarcely perceptible difference for the different times of the day, such slight difference as was noted being in accordance with the accepted doctrine of a rise in temperature towards the middle of the day, and a fall towards night; but the evening temperature (7 P.M.) was not so high as that at two o'clock. A reason for this may be looked for in the fact that the latter time was after a meal; but the effect of so slender a meal as lunch must have been very small indeed, since on several occasions when observations were taken before and after dinner (a heavier meal, but without alcohol) the difference of temperature was only 0.2° (0.3° in the month). On the other hand, the difference of the rectal temperature before and after breakfast was 0.4° in the month, the difference rising to 1.1°.

¹ A paper read before the Physiological Society on Jan. 26th, 1895.

Taking now the three yearly averages for the different weeks separately, and so forming an annual temperature curve, a similarly slight degree of total variation is seen. It appears that the highest sustained average temperature occurred in the winter and early spring months, as may better perhaps be seen by taking four weeks together, when we obtain for these lunar months, commencing in the middle of June, the figures 98.75°, 98.75°, 98.80°, 98.72°, 98.80°, 98.89°, 98.92° (December), 98.90°, 98.97°, 98.90°, 98.95°, 98.82°, and 98.85°. This result is in agreement with what we might perhaps expect, since in cold weather loss of heat must be more rapid, and so a higher level of temperature should be maintained to compensate for increased radiation, just as small animals, which lose heat more quickly in proportion to their bulk than large ones, have generally higher temperatures. Before leaving this part of the subject it may be noted that the temperatures in the mouth and rectum respectively bore to one another a very variable ratio, the latter being almost invariably the higher, with an average difference of 0.8°. Thus on some occasions, as immediately after eating, the temperature in the mouth exceeded that in the bowel; while on others, as during vigorous exercise, the heat of the mouth sank considerably—e.g., to 96°—that of the rectum rising to 99.8° or 100°.

Coming to the pulse-rate, one fact which was well marked was the regular fall in frequency throughout the day, the average number of beats at each of the four times of observation mentioned being respectively 88 (72), 86 (71), 80 (67), and 77 (64), the numbers in parentheses being those taken in the sitting position, the others standing. A steep rise in pulse-rate appeared to occur at breakfast time, the average rate before this meal being, on the few occasions when it was observed, 80 (64), and after breakfast 89 (73). The heart would thus appear to tire slightly with its work during the day and to recover its energy by the night's rest, being thus at its best in the morning, as seems to be the case with the mental faculties and perhaps with all the functions of the body; one might even suggest a causal connexion. The ratio between the pulse-rates taken in the sitting and standing positions respectively varied within very wide limits, the difference being on some occasions not more than three or four beats and at others as many as thirty, without any apparent reason. The average difference for the whole time was fifteen beats. It occurred to me that atmospheric pressure might have some influence on the rate of beat, but a comparison of the pulse-rates for the different weeks with the readings of the barometer did not give any definite result, though during a sojourn in Norway, when staying at very different altitudes for successive weeks, there appeared to be a tendency for the pulse-rate to fall with the barometer, very low frequencies being found at high altitudes, and also on many occasions very low temperatures; but this correspondence may well have been a mere coincidence.

On hearing the above notes Professor Burdon Sanderson was good enough to call my attention to the observations of Professor Jürgensen² on body temperature, and also to lend me the paper in which these are published. These experiments were carried out under very different circumstances from my own. Several different subjects were taken; they were kept in bed for the most part during the course of the experiments made, and other observations were made at very frequent intervals throughout the day, often several times in a single hour. They thus afford a very exact record of the normal body temperature, free from all disturbing influences such as the ordinary business of life introduces, but it was obviously not feasible to keep a healthy man in bed for experimental purposes for any considerable length of time, so that each series of observations was confined to a space of a few days, and the whole were comprised within one year. Comparing Professor Jürgensen's results with my own, it appears that the average figures obtained by him for the four times of day at which my observations were taken are 37°, 37.3°, 37.5°, and 37.3° C. respectively, or approximately 98.6°, 99.1°, 99.5°, and 99.1° F., showing a rather higher level sustained throughout and a maximum towards evening, corresponding to the familiar fact in clinical observation where the conditions are similar. These observations were all taken per rectum.

In conclusion, I may perhaps mention that the times chosen for taking observations in my own case were not ideally the best, but were such as a more or less busy life

rendered possible. It is unnecessary to emphasise the fact that such observations as these made on only one individual can have but a limited value for establishing any general rule, while fallacies owing to the "personal equation" may lurk in making experiments on oneself. My best thanks are due to Dr. Mott for kindly looking through these notes, and for affording me the opportunity of submitting them to the distinguished society before whom they were first produced.

Charing-cross Hospital.

A CASE OF EQUINIA (GLANDERS); RECOVERY.

BY T. W. H. GARSTANG, M.R.C.S. ENG.

THE rarity of the occurrence of recovery from equinia is my excuse for recording the following case. The patient, a veterinary surgeon fifty-four years of age, concluded a period of attendance on a certain horse suffering from "nasal catarrh" of a suspicious type on March 22nd, 1894. On April 4th the animal, having had a relapse, was brought to his house. He administered a "drench" on the spot, and whilst doing so the horse coughed, and a quantity of sputum bespattered his arm and face. This was at 10 A.M., and he, being pressed for time, set off on a professional journey without washing. The arm felt "uncomfortable" the same night, and the patient had "felt ill" ever since. It was not until April 12th that I was called in, and on this date I was consulted for a pustular rash on the right arm, said to have appeared the day before. The above history was not at that time given to me. The case was treated with compound sulphur ointment. On the following day the patient reported his arm as "better." On the 14th he had gone out when I called, and I did not see him; but he had left a message that he was still "better." On Sunday, the 15th, I was sent for at midday, and was then for the first time able to make a complete examination. The man was practically covered with pustules from head to foot. The face and scalp had a few, the chest and back more; but the extremities suffered most; the inner surfaces of the arms and thighs were very bad, but the right thigh was the worst of all. Here the skin was completely covered with pustules in the following stages: small, hard lumps forming subcutaneously, the size of a pea or bean; similar lumps burst and discharging pus; others scabbed over; and, finally, foul ulcers of various shapes and sizes where the scabs had separated. The most intense burning and itching were complained of. The extremities were said to feel as though "wrapped in blankets through which scalding water was being poured." Rubbing and scratching were incessant, although that only aggravated the pain. The pustules were appearing in rapid successive crops, about twelve hours sufficing for a given one to run through the whole of the stages mentioned above. The patient, though much prostrated, refused to go to bed, and managed to keep on his feet. I gave him a strong dose of iron and quinine, and feeling sure that he had not more than a few days to live arranged that Dr. D. J. Leech of Manchester should see him on the following day. On this day, the 16th, there was a discharge from the nose and eyes, and the legs were so greatly swollen that the patient said "they felt as if they would burst." Boric acid dissolved in Carron oil was ordered locally, with a nasal douche of Condy's fluid, and the iron and quinine were to be continued. On the following day the patient appeared slightly easier. During this time he was taking a large quantity of brandy, and by the 20th I had to administer large doses of bromide. Improvement, however, continued slowly in the local symptoms, though the patient still refused to go to bed and was very obstinate about treatment of any kind. Sometimes he would refuse to take his medicine or to obey orders in any way. By the 24th the rash had disappeared from the arms, leaving only red and purple stains to show where it had been, and the legs were improving. On the 25th a large quantity of pus was expectorated from the lungs; also on the 26th. The nasal discharge had increased. His strength was greatly impaired. On the 28th a quantity of sputum was collected and sent to Dr. Leech for bacteriological examination. By May 2nd the rash had disappeared everywhere, and the nasal discharge and expectoration of pus had ceased. On the 11th I

² Die Körperwärme des gesunden Menschen; Studien von Professor Dr. Jürgensen. Leipzig, 1873.

discontinued my visits, as he would do nothing he was told. From the 17th to the 22nd he resumed his professional work, getting about with some difficulty in his gig. On the 23rd I was sent for again. I found the patient suffering from nasal discharge and a rash on the arms and body, very much like that first seen on April 12th, with some pustules and ulcers on the legs. The original treatment was resumed, and by the 28th the symptoms were all abating. Finally, on June 4th, he expressed himself as "quite well," although a few scattered spots still remained; but they were causing him no trouble or inconvenience. Since that date I have not seen him professionally; but he has resumed his ordinary work. The bacteriological examination resulted negatively.

Remarks.—I attended a fatal case of farcy in August, 1885, which was reported in THE LANCET of Oct 24th, 1885; and although there is a sharp contrast in the clinical histories of the two cases there are one or two points of agreement. The causation was the same—viz., the contact of the virus of a diseased horse with the unbroken skin of the right arm, and the omission to wash the arm immediately afterwards. The period of incubation in this case was seven days exactly; in the previous case the patient was also ill in seven days, though nasal trouble did not supervene for sixteen days more, and it was twelve days after that that the first "farcy bud" formed. The patient in the first case died in forty-eight days; the patient in the present case was convalescent in thirty-seven days, with a relapse on the forty-eighth day, and final convalescence in sixty days. I am convinced from observation that the eruption in both cases was of an identical nature, although in the one it was scanty and slowly developed, in the other profuse and running a rapid course. The patient in this case was a veterinary surgeon in large practice. He diagnosed glanders for himself, and abandoned all hope of recovery. It will be interesting to record his own opinion of the disease in the horse. He said it always commenced in "nasal gleet," from which the animal might recover; but that when the gleet "ran on" to glanders or farcy recovery was impossible. The horse which is supposed to have infected this patient recovered. On this argument being used in objection to his diagnosis, he said that a horse suffering from nasal gleet may be placed in a stable with two healthy horses, and one of them may immediately develop glanders and the other farcy, and both die, while the horse suffering from nasal gleet will recover, never showing anything more than that discharge. In other words, a non-fatal case of gleet may be the immediate and direct cause of a fatal case of either glanders or farcy; and this, he declared, was well known among veterinary surgeons. My patient was seen by Mr. Parcell, M.R.C.S., of Ballyneen, co. Cork, on May 1st (an accidental visit by an old personal friend), who agreed with the diagnosis, and candidly informed his friend that recovery was impossible. He was also seen during the course of his illness by others qualified to form an opinion—e.g., horse-dealers and persons who had had practical experience of glanders in the horse; and they all took the same view as Mr. Parcell. I showed the patient to a medical confrère on April 18th and to the medical examiner of an insurance society on April 28th; these gentlemen had not seen a case previously, so their opinions may perhaps not carry much weight, and I will therefore only say that they expressed full agreement with the view of the case which I put before them. Moreover, Dr. Leech on March 16th had no doubt of the nature of the case, and quite agreed with me that the prognosis was most unfavourable. I am careful to place on record the whole of this indirect evidence, because the failure of the bacteriological examination may seem to place the case among those considered "doubtful"; but it must be remembered that the sputum examined was collected only on April 28th, when there was to the naked eye already great improvement on the purulent condition which had existed on the 25th and 28th, and when the general condition of the patient had been steadily improving for twelve days. When I first saw him on April 12th I was only shown the right arm, and the rash was very like one which had puzzled me a fortnight previously, and which turned out to be scabies; hence the first prescription of compound sulphur ointment. For the remainder of the time the treatment was never varied from that ordered on April 16th, except by the vagaries of the patient, who occasionally refused his medicine, but on his own account consumed large quantities of brandy. The urine was non-albuminous throughout. Headache was for many days intense. There was no vomiting. The nasal discharge was troublesome for about a fortnight. The sputum

for a few days seemed to point to the formation of pustules similar to those in the skin in the internal mucous surfaces. There was threatened erysipelas of the face, but it subsided. The genuineness of the case is certain to my own mind after watching it closely. The recovery is undoubted. If it was probably spontaneous rather than due to the remedial treatment employed, still, as there is no specific known, I shall, if I ever have to treat a third case, use the treatment here detailed, not forgetting a free allowance of alcohol.

ST. BARTHOLOMEW'S HOSPITAL.

A CASE OF OBSTINATE PLEURITIC EFFUSION WITH
NEGATIVE PRESSURE IN THE PLEURA; ACCIDENTAL
PNEUMOTHORAX; RECOVERY; REMARKS.

(Under the care of Dr. SAMUEL WEST.)

A YOUNG WOMAN aged nineteen years was admitted into St. Bartholomew's Hospital on Dec. 13th, 1894, with a history of occasional sharp pain in the left axilla, which she had felt for a fortnight. About ten days later she felt ill and shivered several times, and since then had had a cough with a little expectoration. She had been confined three months before, and had suckled her child till the day before admission. She looked poorly, but not ill. Her temperature was 100° F., and she presented the physical signs of a small pleuritic effusion at the left base. There was no bulging of the side or displacement of the heart. By Jan. 2nd, 1895, the fluid had increased so much that the lower two-thirds of the chest, back and front, were dull, and the heart was displaced so that the cardiac dulness extended an inch and a half to the right of the sternum. Paracentesis was performed with an ordinary trocar and long tube to the floor. Manometer pressure indicated four inches negative pressure of water with half-inch respiratory oscillation. No fluid was obtained, although the needle was evidently in a cavity. Air gained access to the pleura, and as the aspirator was not employed no fluid was removed. On Jan. 5th the patient was not so well, being depressed, nervous, slightly feverish, and with a good deal of dyspnoea. The physical signs were those of pneumothorax, the heart being displaced still further to the right and the stomach resonance absent, and a well-marked succussion splash obtained. Paracentesis was again performed in the same way. The manometer registered this time a positive pressure of four inches and a half of water, with a respiratory oscillation of an inch and a half. Ninety-seven ounces of clear serous fluid passed through the tube into a vessel placed on the floor about eighteen inches below the level of the puncture in the chest, with great relief to the patient. On removal of the cannula pressure was applied with strapping to prevent subcutaneous emphysema. The fluid was nearly solid with albumen and formed a little clot on standing. From this time recovery was rapid. The fluid did not form again and the air was very rapidly absorbed, so that five days later, except for a little dulness at the left base behind and slight hyperresonance over the upper parts in front, there was little to note. The breath sounds, though not equal to those on the opposite side, were distinct. By the 14th she was allowed to get up, and on the 21st she was ready to go out. The physical signs had completely disappeared, except for slight impairment of percussion at the base behind.

Remarks by Dr. WEST.—The case is interesting as showing how rapidly air is absorbed from the pleural cavity even when it has been some time inflamed, and how rapidly the lung may re-expand. The pleural pressures are interesting. That a negative pressure of as much as four inches of water should exist with an increasing effusion is, I confess, to me almost inexplicable. I was, unfortunately, not myself present

when the paracentesis was performed. Still I have no reason to doubt the statement made that that was a correct reading, and I record it as what must be accepted. I think, as a fact. It is certainly confirmed by the failure to obtain fluid and by the passage of air into the side. This could not have happened with a positive pressure of such an amount. That the negative pressure of four inches should be converted into a positive pressure of four inches and a half is due to the rapid increase in the amount of the fluid after the first dry puncture, as was shown by the fact that three days later ninety seven ounces of fluid besides much air were removed without suction from the side. I suppose that this acted as a mild irritant to the pleura, much as iodine does. It for the time excited fresh inflammation and effusion, which, however, were followed by very rapid resolution of all, both recent and prior, mischief. Although the introduction of air in this case was accidental, while in other cases its introduction has been intentional, the rapid resolution of what appeared to be an obstinate effusion shows that the admission of aseptic air into the pleura may be in certain cases not only a justifiable but even a very successful method of treatment of chronic effusion.

SAFFRON WALDEN HOSPITAL.

A CASE OF LEFT PYONEPHROSIS; INTESTINAL OBSTRUCTION;
UNUSUAL SYMPTOMS; NEPHRECTOMY; RECOVERY;
REMARKS.¹

(Under the care of Mr. HEDLEY BARTLETT.)

THIS case is one which presents many points of interest to the surgeon. The hydro-nephrosis appears to have followed cicatricial contraction after injury in the neighbourhood of the pelvis of the kidney, but the exact nature of this injury remains uncertain. The reason for the comparatively sudden increase in size and formation of pus in the large cyst is not clear, but the change was attended with very acute abdominal symptoms. It was a case in which the destruction of the kidney had been so extensive and complete that nothing would have been gained by any attempt to drain the cyst; all renal tissue had been destroyed, and drainage would only have resulted in a further loss of strength on the part of the patient.

The patient, a girl aged seventeen years, was admitted into the Saffron Walden Hospital on March 26th, 1894, with the history that in March, 1893, she fell from a horse and injured her left side, and had had pain ever since. During the last three months this pain had increased; she had also noticed a swelling in the left loin, which during the last month had gradually increased, until on March 25th it suddenly enlarged still more. Vomiting set in, and shortly afterwards the whole of the abdomen became very distended. She had had no action of the bowels for five days, and complained of difficulty in passing urine. On admission to hospital the temperature was 102° F., the respiration hurried, the pulse 100, and the skin sweating. The patient was a strong, healthy looking girl; she was lying on her back suffering from paroxysms of pain, and vomiting a biliary material. The whole of the abdomen was much distended, and in the left side, extending posteriorly into the left ilio-costal space and downwards to the left iliac fossa, was a very large, hard, nodular, semifluctuating swelling, which was dull on percussion and could not be easily moved as it was fixed in the ilio-costal space. The dulness was not quite so perfect anteriorly as in the space owing to the colon being distended with flatus. There was a line of resonance between the spleen and the tumour; the hand could also be dipped down between the lower limit of the swelling and the pelvis. Pressure over the swelling in front gave pain, but pressure behind in the ilio-costal space gave marked relief. On vaginal examination the ovaries were found to be normal, and the sound passed into the uterus the normal length. On sounding the bladder no stone could be felt. Dysuria was present; the urine was scanty and alkaline, containing a large quantity of pus. The catamenia were regular. The nature of the swelling was obscure. Was it a tumour from accumulation of fecal matter in the colon or sigmoid flexure? Were the abdominal pain and colic intestinal or nephritic? Was the swelling a large fecal abscess? Mr. Hedley Bartlett considered that if the nature of the tumour had been either of these there would have been more marked febrile

disturbance, the intestinal symptoms would have been better marked, the position of the swelling would have been more iliac than in the ilio-costal space, and the vomiting more troublesome, probably stercoraceous in character. Was it an ovarian tumour? Was it a large lumbar or peri-nephritic abscess? There were no signs of spinal trouble, thus excluding lumbar abscess. All the physical signs pointed to pyonephrosis, hydro-nephrosis being at once excluded by the presence of pus in the urine. The diagnosis was that of pyonephrosis. The sickness continued, and as the bowels were not relieved a large enema was administered. The patient's condition was such that an operation was recommended and agreed upon. The usual lumbar incision was made, and a large, tense, hard, bulging cyst exposed. This was tapped; the contents were first a small quantity of pale limpid urine, followed by sixty ounces of pus and urine having a distinctly fecal odour, suggesting that the colon had been opened. The finger and then a probe were introduced into the kidney cyst to explore for a stone, but the result was negative. The cyst being in such an advanced condition of disease, it was thought best to remove it instead of using drainage. The remains of the kidney cyst were carefully dissected from the surrounding structures to which it was adherent, the ureter was tied, and then the kidney vessels. A large drainage-tube was inserted into the space occupied by the tumour anteriorly, and another in the direction of the pedicle posteriorly. The wound was then sutured. The patient went on well for two days; on the third day, March 29th, she was very sick and became jaundiced. She had passed very little urine since the operation, the skin was dry, and the temperature normal. She was very thirsty and drowsy. On the 30th unusual symptoms set in. The patient was quite insensible and more jaundiced; the pupils were dilated; the tongue was dry and furred, and the breath offensive. She had slight convulsions and vomiting; the bowels were not yet relieved. The temperature was subnormal; she had a distressing hiccough. She passed about twenty-five ounces of urine. On the 31st the patient was still in much the same condition. She was fed on nutrient enemata and suppositories every two or three hours. The temperature was still subnormal; coma was well marked and the skin deeply jaundiced. About thirty ounces of urine were passed. As there was no improvement the patient was placed for from ten to fifteen minutes in a very hot bath and then in hot blankets, and pilocarpine injections administered. Half an hour after the bath she began to sweat profusely, and about an hour after it began to rally. The temperature went up to 103° 6'; the convulsive twitchings lessened; the patient moved when spoken to, but was not yet sensible. An hour later she recovered consciousness. The patient now made a rapid and uninterrupted recovery with no further complications. By the end of April the wound had healed and the urine was normal.

Remarks by Mr. HEDLEY BARTLETT.—The cause of the pyonephrosis in this case was probably some injury to the upper end of the ureter or pelvis of the kidney, causing hydronephrosis, and then pyonephrosis due to intestinal flatus diffusing into the cyst. The sudden onset of urgent symptoms was probably due to some sudden blocking of the ureter, with rapid distension of the cyst. The five days' constipation before the operation was probably reflex in origin (not due to pressure). The ureter was evidently patent at times, otherwise there would have been more inconvenience and ill-health. The vomiting before the operation was also probably due to some form of intestinal poison circulating in the blood, not due to any mechanical pressure on the intestine. The symptoms after the operation were as follows: For two days there was satisfactory progress, between twenty-five and thirty ounces of urine being passed daily. There was no shock. The jaundice and vomiting developing on the third day after the operation and lasting three days were probably due to some form of poison being absorbed secondary to the constipation (? ptomaine poisoning). The coma was not uræmic in origin, as the patient both before and after the operation passed between twenty-five and thirty ounces of urine. The convulsions were also due to the same cause. It is an interesting point that the jaundice, the vomiting, the coma, and the convulsions all came on the third day after the operation and lasted three days. All these symptoms were relieved by purgation, enemata, and a hot bath with hot packing; clearly the symptoms were not uræmic in origin. It is also worthy of notice that the menstrual period had been over a week before the patient was taken ill. The

¹ Read before the Cambridge Medical Society, Nov. 2nd, 1894.

patient continues in good health. The specimen removed, when examined, showed simply a large suppurating cyst; there were so many adhesions round the upper end of the ureter that it was difficult to ascertain the nature of the injury.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Adjourned Discussion on Affections of the Nervous System occurring in the Early (Secondary) Stages of Syphilis.

AN ordinary meeting of this society was held on March 12th, Mr. LANGTON, Vice-President, being in the chair.

Before the adjourned discussion was commenced Mr. HUTCHINSON said that he desired to bring before the meeting some pathological observations which had recently been published by Dr. Laing of Paris on the acute form of paraplegia occurring early in syphilis. The patient was a workman aged fifty, who was admitted with paraplegia of a fortnight's duration. He had still the syphilitic eruption fully out over his body and the history was that infection had taken place a year previously. Weakness in the legs developed suddenly, and fourteen days later the paraplegia was complete and absolute, involving both bladder and rectum, and bedsores developed rapidly. He died suddenly, and the spinal cord was examined at once. A picture of a section of the cord in the dorsal region was shown. The investing membranes appeared normal to the naked eye. There was a development of colloid masses in the substance of the grey matter in the perivascular spaces around some of the larger vessels. In addition there were small, narrow areas of the cord which were undergoing degeneration, and these areas radiated inwards from the cortex towards the centre of the cord. The vascular meshwork of the pia mater was found on microscopical examination to be infiltrated with inflammatory cells; in the arteries there were signs of disease, one showing a small gummatous nodule around it, containing a myeloid cell, while others showed thickening of the coats with infiltration around. But the stress of the disease had fallen on the veins, there being large accumulations of inflammatory cells round them, and one was found to be thrombosed. Dr. Laing found these changes in the whole length of the spinal cord. Since the last meeting he (Mr. Hutchinson) had collated the notes of many other isolated cases, and in nearly all they occurred within a year of the infection. So far as his own notes were concerned, he had found a few cases which occurred at a later period of syphilis, but almost all of these were not typical instances of paraplegia. His main point was that the nervous symptoms, like the dermatological manifestations, should be classified according to the date or period at which they occurred.

Dr. ALTHAUS said that the paper which they had met to discuss and which dealt in a broad and comprehensive manner not with isolated facts, but with whole series of important clinical phenomena, had been very much wanted, because the possibility of the early occurrence of such nerve troubles as had been brought under their notice by Mr. Hutchinson was not yet thoroughly realised by the profession. He had met with such cases in which an erroneous diagnosis had been made because it was believed that specific nerve lesions occurred only four or five years after the primary affection. He related a case of hemiplegia which had come on eight months after infection, and had been diagnosed and treated as hysterical, and got steadily worse until specifically treated; and referred to a discussion at a sister society some years ago, in which two years was mentioned as the earliest period when specific brain lesions would become developed. He had himself seen a characteristic form of headache, followed presently by epileptiform seizures and hemiplegia, three months after infection; and related a case in which extensive disease of the cerebral arteries, with softening of brain tissue and other characteristic nerve lesions, had become developed three months after infection. He had met with several cases of analgesia in the secondary stage, and thought that this would be more frequently found if it were looked for. Acute multiple neuritis was no doubt sometimes the cause of the more or less general paresis with anaesthesia which was seen in the secondary stage,

but acute encephalitis, ascending myelitis, and poliomyelitis might also occur during that period. He related a case of tabes which had become acutely developed seven months after infection, and where the patient made a very fair recovery under specific treatment. Early neuritis of single nerves was not uncommon, and he had found that the portio dura was more apt to suffer thus early, while in the tertiary stage the third nerve was more frequently affected. He had also seen neuritis of the sixth and of the ulnar nerves four and six months after infection. He then discussed the question whether there were any predisposing or exciting causes of early nerve syphilis, and said that he had seen it where the primary and secondary symptoms had been unusually mild, and also where they had been severe, so that the greater or lesser virulence of the initial symptoms did not seem to be of much influence. Specific treatment was, however, apt to be unduly neglected in mild forms of the disease. The two principal predisposing causes had appeared to him to be youth, for all his cases had occurred in young people, chiefly between eighteen and twenty-nine, and injury to the head, whether received previously or subsequently to infection. Other predisposing causes were neurotic inheritance, sexual and alcoholic excesses, and undue strain on the mind. The chief differences between early and late nerve syphilis appeared to him to lie neither in the nature of the lesions, for arteritis and syphiloma occurred both early and late, nor in their seat, as no portion of the nervous system appeared to be safe from the inroads of the virus at either period. Early nerve troubles were, however, more acute in their appearance, and more amenable to specific treatment, while tertiary affections had a slower and more insidious course, with a tendency to end in general paralysis. Nervous affections after the acute exanthemata, such as paralysis, the delirium of collapse, &c., might appear at a still earlier period—that is, before or immediately after defervescence; while a considerable interval between the cessation of the fever and the appearance of nerve troubles was exceptional. Influenza stood very much in the same line with the eruptive fevers in this respect. He had seen a few cases of what he might call tertiary nerve affections after influenza, but in no case had the interval between their appearance and the primary attack exceeded six months; while insanity, general paralysis, encephalitis, myelitis, and neuritis had frequently followed the attack at a very short notice. In conclusion, Dr. Althaus spoke strongly about the necessity of the full use of mercury in the cases under consideration. He preferred the hypodermic use of the metal, and injected the soluble perchloride, which was readily absorbed and eliminated, in acute and threatening cases, and an insoluble preparation, where the mercury was rubbed up with carbolioil and lanoline, in the more chronic forms of the disease. The latter preparation was slowly absorbed and eliminated, and need only be injected once a week, while the perchloride should be injected daily for some time. No other remedy could be relied upon with such confidence in the gravest emergencies of this kind which might come under our notice, although even mercury was not infallible.

Sir WILLIAM BROADBENT said that his own contribution to this debate would be a very modest one. Though none who had heard the speech of Dr. Gowers could regret that it had been delivered, yet it had ranged wide of the subject matter laid down for debate in the introductory remarks of the President. The President had done well to rehearse the important clinical facts of the second and third stages of syphilis and the effects in these stages of iodide of potassium and mercury in treatment. He did not think that morbid anatomy could ever have convinced us that the manifestations of the third stage of syphilis belonged to the same disease and were produced by the same poison as the manifestations of the first and second periods; and if we extended our definition of the tertiary stage to include locomotor ataxy and general paralysis of the insane pathological anatomy would have been still more at fault. He agreed with Dr. Gowers that the ultimate clue to the diversities in this disease would eventually be found by an inquiry into the causative microbe or microbes and their toxins. The secondary lesions were characterised by their symmetry; the tertiary by their want of symmetrical grouping. The secondary lesions were caused by a disturbance of nutrition on the side of the blood; the tertiary lesions, on the other hand, were tissue changes initiated by blood changes, but which had ceased to have any immediate relation to blood changes. With reference to the production of therapeutic effects,

at present we had to rely merely on the observed effects of drugs, but later remedies would be applied not merely from a known experience of the effects of the drugs, but there might be an actual biological explanation of their action. He confessed that from his early work he had been of opinion that the effects of secondary syphilis were manifested upon the skin, mucous membranes, and bloodvessels, and were seldom of a destructive character. The tertiary lesions, besides involving the tissues in these situations, also involved the deep-seated viscera and nervous system. The late manifestations of syphilis were attributed either to the results of damage to the vessels done during the secondary period or to gummatous growths. Hence when he came across paraplegia during the first two years of syphilis he had been in the habit of looking upon it as a precocious tertiary manifestation. He referred to the case of a patient aged twenty-four who came under treatment last October, six months after the chancre signs of paraplegia began to show themselves. Another man, aged forty, came under treatment in July, 1894, with definite signs of paresis; he had acquired syphilis a year previously. These cases were clearly due to the effects of secondary syphilis upon the spinal cord, and he regarded it as really a myelitis and not a primary affection of the vessels. He had seen epilepsy in the second stage of syphilis which had yielded to treatment, and there was no recurrence after twenty years. Certain cases of spinal meningitis he had also attributed to secondary syphilis. In one such case there were pain and ataxic gait in the legs and in the arms rapid wasting of the muscles; the meningitis seemed to have affected the posterior aspect of the cord at the lower part and the anterior aspect of the cord at the upper part. Recently he had seen two cases in which a zone of anaesthesia rapidly developed.

Dr. FERRIER said that all neurologists looked upon syphilis as one of the most potent factors in diseases of the nervous system. The lesions might occur at any time; those which came under his notice were usually in the later stages of syphilis. He was not prepared to admit that syphilitic diseases of the nervous system should be separated into a distinct—a nosological—group. Jacksonian epilepsy was frequently caused by syphilis; so were hemiplegia, hemianesthesia, and Bell's paralysis; and so also were the affections of the spinal cord which had been recently erected into a special group by Erb. He knew of no way of distinguishing these cases from others which were not syphilitic. He quoted five cases of the gradual type described by Erb. The first was a man aged thirty-five years who developed the symptoms two years after the chancre; the second, in a man aged forty-four, began a year after the chancre; the third, in a man aged forty-four, began ten years after the chancre; the fourth, in a man aged forty-four, began six months after the chancre; and the fifth, in a man aged forty-one, began thirteen years after the chancre. He then referred to five cases of sudden acute paraplegia. The first, in a man aged twenty-five, began six months after the chancre; the second, in a man aged twenty-five, began eighteen months after the chancre; the third, in a man aged about thirty, began eight years after the chancre; the fourth, in a man aged thirty-two, began two years after the chancre; and the fifth, in a man aged twenty-three, began three years after the chancre. He then mentioned three other cases in which the disease was of the gradual type and in which there was no history of syphilis, the first being in a man aged forty, the second in a man aged thirty-three, and the third in a man aged sixty-one. These three last cases corresponded precisely with Erb's syphilitic group. Sudden paraplegia occurring in syphilitic individuals might turn out to be only the preliminary stage of a disseminated sclerosis; and he referred to two instances, both males, aged thirty and thirty-eight respectively, who illustrated this point. So far as the symptomatology of the spinal lesions went he was unable to distinguish the syphilitic from the non-syphilitic cases.

Dr. GEORGE OGILVIE quoted a number of statistics to show that the lesions of the nervous system to which Mr. Hutchinson had alluded had been recognised for more than twenty-five years as occurring in connexion with syphilis; that the symptoms often came on within a few months of infection, and hence belonged to an early stage of the dyscrasia, and all alleged that the disease showed a tendency to improvement, if not to recovery. He gave a list of the single cases of nervous disease occurring early in syphilis which he had been able to collect, and he referred to large series of figures by Fournier and others showing that a considerable percentage of the

nervous troubles ensued within a year from infection. The specific dorsal myelitis which had been described was only one of the many nervous manifestations of syphilis that might occur early, and though the myelitis was more common in the early stage, yet it might occur also later. It had been said that these early lesions were symmetrical, but the symmetry was due to the seat of the affection; it was symmetrical because it was spinal rather than because it was secondary. The affection of the brain and of single nerves showed no tendency towards symmetry. There were two other transitory nervous symptoms often observed besides the analgesia which Mr. Hutchinson had described—an increased irritability of the superficial and deep reflexes, and a hyperæmia of the optic discs; the latter was said to occur in 30 per cent. of syphilitic patients. The irritability was probably to be explained by an alteration in the blood-supply of the nervous system similar to that to be witnessed in the optic disc. The analgesia, he thought, might be of hysterical origin.

Mr. COTTERELL said that the primary infection might be so mild that it would escape notice and the patient would then deny the history of syphilis. A man aged twenty-seven, giving no history of syphilis, presented in 1890 nodes on the clavicle. In 1894 he had an epileptic fit, there was blurring of the left optic disc, and the left lower extremity was weak. He thought that locomotor ataxy and general paralysis were not truly placed in the tertiary stage of syphilis, but really should be regarded as forming a fourth stage.

Dr. F. J. SMITH mentioned the case of a man aged twenty-eight who had suffered from a chancre eighteen months before the appearance of the symptoms. In July last he was stunned after a fall from a cart; later he developed a condition of typical paraplegia. The symptoms appeared to be due to neither a vascular nor a gummatous change, but were probably produced by a diffuse infiltration of leucocytes. He should describe Dr. Ferrier's cases of disseminated sclerosis as typical of syphilis; certain damaged areas had gone beyond the reach of iodide of potassium and mercury, but had not been absolutely killed; in these areas a slow sclerotic change had occurred, producing the symptoms complained of.

Dr. MOTT described a case which had been admitted into Charing-cross Hospital six years ago, the microscopical sections from the spinal cord of which were precisely like the drawings which had been shown. The patient was a man aged twenty-three, who was admitted with a typical "focal" myelitis; he had had syphilis less than two years before the onset of these symptoms. He died from an acute spreading bed sore, and at the necropsy myelitis was found, there being congestion of all the vessels with leucocytes in the perivascular spaces.

Dr. PARKES WEBER mentioned the case of a man aged forty-two who was admitted to the German Hospital in September, 1894. There was a history of chancre one year before, and on examination paraplegia was found, but it was unaccompanied by loss of sensation. He died from a large bed sore, and at the post-mortem examination the substance of the cord in the lower dorsal region was found to be softened.

Mr. HUTCHINSON, in reply, commented on the interest of at least three observations to the effect that in cases of paraplegia in which sensation was not lost nevertheless bed sore developed. One outcome of the debate was a strong emphasis of the fact that a majority of the cases of the nervous manifestations of syphilis did occur in the early periods. He knew that many such cases had been recorded, but they had nearly all been described as precocious tertiary manifestations. If we attempted a natural definition of syphilis we should describe the second stage as the blood stage, during which the patient should not marry, as he was still liable to infect his wife and his offspring. If this definition were accepted, then what Fournier and others regarded as manifestations of a tertiary stage we would call secondary, or at any rate "blood stage," cases. Dr. Gowers appeared to regard the tertiary phenomena as due to a chemical poison left behind by the syphilitic microbe. He himself regarded the tertiary phenomena as local phenomena due to an implication of cell structures and leading to cell growth; but this did not imply the existence of a poison still circulating in the blood; he did not believe that the blood was infected in any way in tertiary syphilis. Dr. Gowers had implied that the syphilitic remedies were not so useful in the purely inflammatory manifestations of syphilis, but in the inflammatory affections of the skin mercury certainly was

very useful. Dr. Ferrier's more typical cases of acute paraplegia appeared to occur during the early period of syphilis. The advisability of forming a special group of these syphilitic nervous manifestations had been doubted; there was no doubt that they were not absolutely special to syphilis, for he had often held that syphilis imitated but did not create, yet, nevertheless, as with skin syphilitic troubles, there were peculiarities about them which enabled skilled observers to say that they were probably syphilitic, and for that reason they were worthy of being put in a separate class. He had seen very few cases of acute paraplegia which were non-syphilitic and which recovered.

MEDICAL SOCIETY OF LONDON.

Hysterical Deafness.—Thirty Cases of Nephrorrhaphy.

AN ordinary meeting of this society was held on March 11th. Mr. H. H. CLUTTON, Vice-President, being in the chair.

Dr. HECTOR MACKENZIE read a paper on a case of Hysterical Deafness, with remarks on the diagnosis and treatment of this affection. He said little was to be found on the subject in the ordinary text-books, and very few cases had been recorded. Some authorities were sceptical as to the real existence of the malady. He thought it was important, therefore, to bring forward a case which did not admit of doubt, to refer to the points of importance in arriving at a diagnosis, and to call attention to the mode of treatment which had proved successful. There was a pretty general agreement in the accounts of the malady given by Politzer, Gruber, Hartmann, Briquet, &c. to the effect that hysterical deafness did exist, but was decidedly uncommon, and that it was usually unilateral, accompanied by hemianæsthesia, transferable from one side to the other, and of variable intensity. Jolly was almost alone in allowing that it might affect both ears, which was the case in Dr. Mackenzie's patient. The question of bone conduction of sound was one of great importance in the diagnosis. Hartmann and Walton observed greater impairment of bone than of aerial conduction. In Dr. Mackenzie's case both were equally affected, and this was what would *a priori* be expected in a malady where the impression-receiving and interpreting brain was at fault and not the organ of hearing itself. A case published by Ouspensky of Moscow seemed to show, however, that sometimes the bone conduction was not impaired. The important points in making the diagnosis of hysterical deafness were these: (1) the association of deafness with undoubted symptoms of hysteria; (2) the sudden development of the deafness after some emotional disturbance or shock or after trauma; (3) the absence of any sufficient cause for the deafness in the auditory apparatus itself as shown by the ordinary methods of examination; (4) the impairment of bone conduction of sound to at least as great an extent as aerial; and (5) the frequent coexistence of anæsthesia of the pinna and external meatus. The history of the case was as follows. The patient was a girl aged sixteen years. In November, 1891, she had a sore-throat during an undoubted outbreak of diphtheria at a boarding school. At the end of January, 1892, she had a slight attack of influenza. As she was suffering from earache after this attack her medical attendant Politzerised her. The girl screamed, and from that moment was extremely deaf. The medical attendant said he had perforated the drum. For some days the left ear discharged copiously a green fluid. About a week later the girl was taken to see an aural surgeon in London, who said he could see where the ear had been perforated, but that it was then healed. Galvanism was ordered locally and strychnine internally. Presently numbness in the limbs set in, so that the girl was anæsthetic all over except on the head and neck. She also lost power both in the legs and arms. For six months she was treated in London with massage and electricity, and gradually recovered sensation and power until she could use her hands perfectly and sew and write. She continued unable to hear, to raise herself, and to use the legs. The treatment was continued at Droitwich and Weston for two months longer without further improvement. From October, 1892, to March, 1893 she was at her home in Wales and remained in the same condition. In March, 1893, she was admitted to St. Thomas's Hospital. She then underwent a course of Weir-Mitchell treatment for ten weeks, with the result that she gained 22 lb. in

weight, but without any impression either on the paralysis or the deafness. At the end of the time it required about six assistants to prop her up in the upright position, and to drag and push her in this position across the floor. As she had some power in her arms a gymnasium suit was obtained for her and she was taught by degrees to walk on her hands while the legs and body were supported. After a great deal of perseverance and the contrivance of various exercises, she gradually regained the use of her legs and recovered strength in her back. Progress was interrupted by an attack of scarlet fever in October, but on recovery from that none of the ground gained had been lost. The deafness at this time still remained unchanged. With the right ear the patient could hear nothing, but with the left she was able to hear a very little. Nothing abnormal could be detected on examination with the speculum. Bone conduction was apparently absent in the right and nearly absent in the left ear. The treatment of hysterical deafness recommended in most of the text-books was electricity locally. Briquet had said he had never known this to fail. It was said by some, Cure the other symptoms and the deafness will disappear, but others said it tended to remain unless treated. Here the other symptoms had been cured, and in spite of local blistering and galvanism the deafness still remained. Seeing it had been set up by Politzerisation local treatment did not seem advisable. Everything recommended in the text-books had thus been tried without effect and the deafness had lasted nearly two years. The mode of treatment which in the end proved successful was one which had been previously suggested in the *Marseille Médical* by Dr. Gilles. The attempt was made to re-educate the sense of hearing much in the same way as she had been re-educated in walking. The patient was made to listen to and to try to count the ticking of a clock at increasing distances, to listen to and attempt to repeat words and sentences spoken, first close to the ear and then at greater distances. The treatment was commenced on Dec. 21st, 1893. At the first trial the patient could not count the ticks of the clock even close to the ear. Gradually she succeeded and the clock was placed at greater distances. As the hearing improved in one ear, so it did in the other. The same was done with the spoken voice. At first a word was spoken near the ear, and was not heard until repeated six or seven times. After practising ten days in this way she had so far recovered as to be able to carry on an ordinary conversation. A week or two later the hearing had become of normal acuteness. The recovery of hearing was accompanied by great improvement in her mental condition. She became as bright and lively as she had previously been the reverse. It was now more than a year since she had regained her hearing; the restoration of hearing had been permanent and she had continued in excellent health.—Mr. CLUTTON said he had seen cases of hysterical deafness associated with hemianæsthesia.—Dr. HILL said that the diagnosis of functional deafness should not be accepted without great caution. In the instance related there was a strong suspicion of diphtheria, and he thought that perhaps it might be a case of diphtheritic paralysis. There was also a distinct history of traumatism, and the inflation of the tympanum might have been performed in such a way as to cause concussion of the labyrinth and temporary anæsthesia of the auditory nerve. This condition, added to the neurotic element, would serve to explain the symptoms. It should also be remembered that the auditory education of deaf-mutes had been most successful, and that in many of these there was organic disease.—Dr. TURNER said that he was strongly under the impression that the case was one of hysterical deafness. The general paralysis was not of diphtheritic character; it was a case of typical functional general paralysis. It was also interesting to note that the same treatment—namely, education—which had been applied with success to the general paralysis had likewise proved successful in the ear, in which there was no sign whatever of organic disease. The recovery was too rapid to allow of any other diagnosis but that of functional disease. He added that in the majority of cases of hysteria the Weir-Mitchell treatment with isolation was sufficient to cure without a course of physical education.—Dr. SYMES THOMPSON, whilst fully admitting the immense value of the educational treatment in functional cases, yet wished to point out that in real disease of the ear steady systematic education had proved very successful.—Dr. MACKENZIE, in reply, said that it was improbable that the patient had ever had diphtheritic paralysis. Traumatism was a common cause of hysterical affections, but it was doubtful if concussion of the

labyrinth would last two years and then suddenly yield to such treatment as had been described. Dr. Thompson's remarks bore out his contention that cases of functional deafness were really more common than had been generally believed.

Mr. BRUCE CLARKE then read a communication on Thirty Cases of Nephrorrhaphy with their results. He said that the value of operation in this class of cases had sometimes been called in question, and he was anxious therefore to record with the after-history the ultimate results of these thirty operations. Two years ago he drew attention at the Royal Medical and Chirurgical Society to a class of cases of movable kidney which had previously attracted very little notice in this country, cases in which severe pain was a prominent symptom. The pain and other acute symptoms seemed to point to "acute renal dislocation" as the likeliest determining cause. Such cases were only one variety of floating kidney. His experience had shown him that it was rare to come across any case of the kind in which pain had been completely absent throughout, and as to the reality of these attacks of pain when they occurred no one who had seen them could have any doubt. The question to be determined was what was the probability of a successful result after operation. In his own cases the immediate result was successful in every instance, all the patients being alive at the present time. In by far the greater number pain was the prominent symptom, and the severity of the pain had led to the demand for relief. The pain usually came on suddenly, sometimes after a strain or severe exertion, sometimes after injury. It was often attended by vomiting, and later usually gave rise to local abdominal tenderness. The duration varied from a few hours to a day or two, and in some instances it might be cut short by manipulating the affected kidney—in other words, by reducing the dislocation. The condition of the urine during and shortly after the attack varied greatly; it might be scanty and bloodstained or almost porter-coloured, while in the less severe cases it was more commonly unaltered. In some of his cases the pain did not amount to more than an ache aggravated by exertion of any kind. In many cases during the intervals between the attacks the kidney was unduly tender to palpation. The first two cases were the only two instances in which the kidney was surrounded by a well-marked mesonephron, and in which therefore it was necessary to open the peritoneum in order to fix them firmly in position. In the first case the patient fifteen months later stated that she had not had any further pain in the loins. In the second the pain ceased for a few weeks and then returned with greater severity than before, so six months after the first operation he cut down and removed the offending organ in which, after removal, a small calculus covered with minute spicules was discovered. The patient made a rapid recovery and had since had no further trouble. The next case presenting special points for consideration was that of a woman who for over three years had suffered from movable kidney, having been quite invalided in consequence of the pain. The right kidney could be felt at times to be larger than the left. Mr. Bruce Clarke operated on the right kidney and fixed it securely in position. She had also complained of some pain in the left kidney, but this cleared up, and she ultimately recovered perfect health. Four other patients had at some time passed pieces of calculous material.—Mr. CLUTTON said that in some of the cases related it was open to doubt whether the calculus was really secondary to the movable kidney or had preceded that condition.—Mr. LOCKWOOD said that two years since he performed nephrorrhaphy on a woman, who had suffered so much pain from the movable kidney that she became pale and perspired profusely when she exerted herself. Three or four sutures were passed deeply into the kidney, and the patient was at present quite well. A great many of these cases were better treated with a horseshoe pad and abdominal belt, and those suitable for operation were not common.—Dr. H. MACKENZIE said that in the majority of cases the pain was neurotic, and the patients were not benefited by operation. He asked what cases were really suitable for surgical measures.—Mr. WALLIS said that a plea for early operation was to be found in the fact that if the patients were left till late some form of degeneration of the kidney was usually found to have occurred. Mechanical supports were difficult to adapt satisfactorily.—Mr. CLUTTON added that he preferred to use kangaroo tendon for suture, as in cases where silk had been used it had led to an obstinate sinus from the bottom of

which a silk ligature ultimately came away. In the large majority of cases he found that the adaptation of an abdominal belt was successful, and he would only operate in cases where this measure failed.—Mr. BRUCE CLARKE, in reply, said he had adopted suture in cases where much pain was complained of, but nearly all had been previously treated by belts. He cut down, removed the perinephric fat posteriorly, passed a long curved needle through the lumbar fascia and renal substance, and scarified the posterior surface of the kidney to promote adhesion. In all cases he opened the renal pelvis to search for the cause of pain, and passed a bougie down the ureter to the bladder. He believed the condition of movable kidney was the first stage of many cases of hydronephrosis, though he admitted that a large number of these movable kidneys gave rise to no further symptoms.

CLINICAL SOCIETY OF LONDON.

Cerebral Tumour following Injury.—Association of Psoriasis with Diabetes.—Rupture of Gall-bladder and Liver produced by violent Straining in a Patient suffering from Obstructive Jaundice.—Traumatic Cystic Lympho-sarcoma of Shoulder removed by Amputation after Five Years' Growth.—Complete Unilateral Arrest of Development in a Child with Arous Senilis and without Hemiplegia.

AN ordinary meeting of this society was held on March 8th, Mr. LANGTON, Acting President, being in the chair.

Dr. HANDFORD read the notes of a case of Cerebral Tumour following Injury. The patient, a man aged forty-three, had been injured by falling out of a cart upon his head. For the first fortnight he had no definite symptoms; afterwards he became mentally depressed, and experienced gradually increasing failure of muscular power. On admission to hospital four months after the accident there were general muscular enfeeblement, loss of control over the sphincters, and marked mental hebetude. Complete paralysis of the left face, arm, and leg supervened somewhat rapidly, with very extensive optic neuritis. There was headache, but never vomiting or local spasm. From the very close resemblance to a previous case recorded at length in *Brain*¹ a diagnosis was made of tumour, probably sarcoma, arising in the injured tissues and situated on the right side close to the motor tract. The patient was trephined, but the tumour was not found, and at the necropsy shortly afterwards a tumour was discovered 4 in. by 7½ in. in size, firm in consistence and dark in colour, situated behind and to the outer side of the right corpus striatum. Microscopically it was a vascular sarcoma, containing some spindle cells and in places a coarse meshwork filled with uninjured blood corpuscles. Dr. Handford expressed the opinion that the causal relation between the injury and the new growth was undoubted in each case, and that the frequency of such occurrences was somewhat underestimated.—Mr. W. G. SPENCER said that he had read of a case in which a blow on the left side of the frontal lobe caused deviation of the eyeballs and weakness of the shoulder, which developed immediately after the accident and then disappeared. Six months later these symptoms returned and went on to the development of a cerebral tumour. Such a case was an instance of development of malignant tumour in a scar, and it perhaps went some way in confirming Hunter's view that tumours occasionally developed in blood-clot.—Mr. ARBUTHNOT LANE referred to a case showed two years ago by Dr. Pitt and himself. The patient struck the top of his head violently against the corner of a table. Later he felt that the spot on the top of his head was becoming soft. A malignant growth of the dura mater was diagnosed and the growth removed. Up to the present the patient had remained free from recurrence.—Dr. HALE WHITE had recently seen a man with a cerebellar tumour which developed at the site of a blow. Cerebral tumour was more common in males than in females, and it had been asserted that this was due to the greater frequency of blows in the male sex. But an examination of the records of the Children's Hospital showed that in children under five the excess of males over females affected with cerebral tumour was precisely the same as in adults, and therefore the excess was not presumably due to the greater liability of males to injury.—Dr. HANDFORD, in reply, said that his cases resembled each other and differed from those quoted in that

¹ P. 296, 1891.

the symptoms were more or less continuous from the time of the injury and then began rapidly to progress.

Dr. KARL GRUBE (Neuenahr) gave the particulars of cases illustrating the Association of Psoriasis with Diabetes. The first case was that of a man aged thirty-nine years suffering from the hereditary form of diabetes. The psoriasis had existed since his boyhood. It was observed that the psoriasis was less troublesome when the general condition of the patient improved, but while this improvement of the psoriasis lasted the diabetes advanced and death occurred at last from coma. The pancreas was found to be normal; there were secondary changes in the nervous system. In Case 2, the brother of the former patient, aged thirty, the patient had been suffering from psoriasis for many years; the diabetes was only discovered last year. It advanced very rapidly, and now there were the symptoms of the severe form; the psoriasis, on the other hand, had nearly disappeared. The third case was that of a man aged forty years with a history of gout. The patient had been suffering from very troublesome psoriasis for many years. When the diabetes set in some few years ago the psoriasis showed great improvement. Case 4 was that of a man aged fifty-five, who had suffered from psoriasis since 1865. In this case an alteration in the intensity of the psoriasis and diabetes could be observed at two periods. The psoriasis was very bad in 1890 and 1891, then it got better again, but it was found in the spring of 1892 that the patient, who complained of general weakness and loss of flesh, passed much sugar. An improvement of the diabetic condition was attained in the summer of 1892 and lasted for two years, but the skin affection became worse again. Having been treated for the latter in the summer of 1894 with good result, the amount of sugar had increased again since last October, and the patient had to be more careful with his diet. Dr. Grube did not believe that this combination was a mere coincidence.

Mr. W. ARBUTHNOT LANE read notes of a case of Rupture of the Gall-bladder and Liver produced by violent Straining in a patient suffering from Obstructive Jaundice. The patient was a woman aged fifty-four who was under the care of Mr. Reginald Clarke of Lee Park. Apparently in consequence of her having administered to herself an excessive purge, she was attacked with profuse diarrhoea on Dec. 16th, and during a violent expulsive effort she suddenly exclaimed that something had given way in the region of the gall-bladder. This was followed at once by pain, which became rapidly intense. Mr. Clarke found a large rounded tumour projecting the abdominal wall forward and having the relations of the gall-bladder. The motions passed during the day after the onset of the pain consisted almost entirely of blood, being later of what was apparently digested blood. The friends made no mention of this circumstance till after the operation. Mr. Clarke in consultation with Mr. Burroughs urged operative interference as the patient was becoming rapidly worse, and the patient consenting she was removed into St. John's Hospital, Lewisham, for the purpose. Mr. Lane saw her on the 21st, and though she was practically moribund agreed with Mr. Clarke that a relief of the distended condition of the gall-bladder might, even at this period, be of service to the patient. Consequently the greatly distended gall-bladder was exposed, the tumour at once projecting through the incision. It was incised and more than three-quarters of a pint of blood-clot was removed. As it was then found that the common bile and common hepatic ducts were enormously distended by the same material nothing further was done. Dr. Shaw examined the parts and found that the hepatic aspect of the gall-bladder, together with the adjacent portion of the liver, was rent, and that all the ducts in the liver also were filled with clot. In support of his explanation that the rupture had resulted during violent straining Mr. Lane quoted from a paper by Dr. Willard² a case in which death appeared to have resulted from rupture of a distended gall-bladder and from hæmorrhage into the peritoneal cavity. He considered his case to be of sufficient rarity and interest to place before the society. For many reasons it was very difficult to obtain from the friends of the patient any definite details prior to the operation.

Mr. W. G. SPENCER related a case of Traumatic Cystic Lympho-sarcoma of the Shoulder removed after Five Years' Growth by Amputation of the Right Upper Extremity, the flap being taken entirely from the upper half of the arm owing to the skin being widely involved. The patient lived in New

Zealand and was now twenty-one. In 1889 he bruised the right shoulder, which remained painful, and in a few months a soft swelling slowly formed above the clavicle. During more than three years repeated incisions were made and drainage-tubes inserted, the interior of the cysts scraped, and the clavicle removed. He was attacked several times by inflammation, the right arm became swollen, and his general health suffered so that in June, 1894, it was stated to him that an early fatal issue was to be feared. During his voyage to England all the incisions healed, leaving the skin over the tumour marked by scars. All swelling of the arm disappeared, and upon arrival he was in robust general health. He was taken by Dr. Frederick Mounat to see Mr. Macnamara, who, being about to leave town, called Mr. Spencer in. Covering the right shoulder was a tense elastic tumour, which extended from the third rib in the anterior nipple line to the spine of the scapula behind and from the inner border of the sterno-mastoid muscle to the point of the shoulder. It projected upwards from the shoulder to the level of the angle of the jaw, and caused a bulging in the axilla below. All the central dome of the tumour was covered by scars, and there the tumour was more adherent and contained solid matter. At the periphery the skin and deep structures were free and no solid matter was to be felt. The arm was quite natural. In consultation it was agreed that the disease was probably an encapsuled cystic sarcoma, and that it was possible to remove it provided that the encapsulation was confirmed and that the vessels could be ligatured beforehand. Mr. Spencer first made an incision below, raised up the tumour from in front of the upper three ribs, cut across a partially reformed clavicle, and, by taking the third rib as a guide, ligatured the subclavian vein and artery on the first rib. The flap was fashioned by raising all the skin and fascia of the upper part of the arm, the pedicle of the flap being formed by the skin of the armpit and by the posterior axillary fold. The flap thus depended for its nutrition upon posterior cervical and dorsal vessels. The tumour was removed with the scapula, to which it was intimately attached, by shelling out. This exposed the internal jugular vein, the dome of the pleura, which bulged in the root of the neck internal to the scalenus owing to the atrophy of the clavicular portion of the sterno-mastoid after the excision of the clavicle. The main floor of the wound was formed by the sterno-mastoid, scaleni, the cut ends of the scapular muscles, and the upper two ribs. The skin flap from the arm covered in the wound and healing took place well as far as it was concerned; but the skin which had covered the spine of the scapula and acromion, naturally thin, had been in part undermined by the tumour, and this skin slowly became gangrenous. *Pari passu*, however, with the removal of the slough the muscles in the base of the flap atrophied, hence there was enough to make good the loss of skin at the upper and back part of the neck. The intracystic material proved to be a lympho-sarcoma. As shown in the microscopical specimens and drawings the contents of the cystic lympho-sarcoma, cystic from the first, with only a small amount of intracystic material, was excessively rare. It was difficult to understand how the growth could have been otherwise treated even at an early stage; if the skin could have been supplied by transplantation the involvement of the large vessels of the neck in the growth would have led to their ligature, and so probably to gangrene of the arm, had removal of the tumour only been attempted. The patient was about to return to New Zealand and the prognosis appeared to be quite favourable.

Dr. WALLIS ORD related a case of Complete Unilateral Arrest of Development with Arcus Senilis and without Hemiplegia in a girl aged twelve years. There was nothing in the history of the case that suggested any cause for this condition, except that the mother had suffered during her pregnancy from extreme mental anxiety due to nursing an elder child who died from hydrocephalus. The whole of the right side of the body below the level of the eyebrows was distinctly smaller than the left, bones and soft structures being alike affected. Above that level the conditions were reversed. There was no paralysis, rigidity, or contraction; ordinary sensation and faradaic sensibility were unimpaired, and the child's intellect was good. In the right eye there was a thin, sharply defined arcus above and below, and there was also considerable myopic astigmatism. Reference was made to a very similar case published by Dr. J. S. Bury, with very marked hemiatrophy of the tongue. The pathology of the case seemed to be obscure, but Dr. Ord suggested that it was an extremely mild form of the condition known as

² The Transactions of the American Surgical Association, 1893.

infantile spastic hemiplegia.—Dr. J. TAYLOR said that the patellar reflex was usually more active on the hemiplegic side if there was an intracranial lesion of a definite character. He regarded the case rather as a general defect of development of the nervous system.—Dr. WALLIS ORD, in reply, said that he looked upon the case as one of the class of spastic hemiplegia though no actual spasm was present.

OBSTETRICAL SOCIETY OF LONDON.

President's Address.—The Disintegration of Organic Tissue by High Tension Currents.—Exhibition of Specimens.

A MEETING of this society was held on March 6th, Dr. G. E. HERMAN being in the chair.

Dr. F. H. CHAMPNEYS, in his presidential address, made a spirited defence of the action of the society in granting certificates to midwives after examination. He argued that the society only endeavoured to protect their poorer countrywomen from the risks incidental to the employment of ignorant and irresponsible midwives, and that this troublesome and thankless task had been undertaken by them solely in consequence of the apparent non-existence of any authority competent for the duty. He pointed out that the usurpation of medical functions by the women who possessed their certificate could easily be repressed by reporting the facts to the society, as the offenders would be deprived of their certificates in accordance with the undertaking signed by each of them. He said that if the General Medical Council, before formally condemning the work of the society, had explained that the form of the certificate was open to objection the necessary steps would have been taken for its modification and amendment.

Dr. WATT BLACK proposed that the President be requested to allow his address to be printed in the Transactions of the society.

Dr. HERMAN seconded this, and it was carried with acclamation.

Dr. GRIFFITH proposed that a number of copies be printed, so that the address might be circulated among the Fellows of the society, and, at an appropriate date, among members of the General Medical Council and members of Parliament. (The address dealt with the subject of Midwives and their Relations to the Public and the Medical Profession.) This was seconded by Dr. POTTER, and carried.

Dr. J. INGLIS PARSONS read a paper on the Disintegration of Organic Tissue by High Tension Currents. He said that these investigations were undertaken to ascertain the capabilities of electricity as a destructive agent in the treatment of malignant disease. He had found from former investigations that the constant current was only effective at the poles for this purpose even with powerful currents. By using powerful interrupted voltaic currents a much greater area was injured, apparently by the force of the impact. He had some success with this method, but the results varied, some cases being more resistant than others. If the strength of the voltaic current was raised to meet this too much heat and caustic action were developed. It became necessary to investigate further. Having noticed the disruptive effects produced by currents of high electro-motive force, it was decided to have a transformer made to a special design. By this means quantity was turned into pressure, heat and caustic action were reduced to insignificance, while the destructive action was enormously increased. The transformer was capable of working up to 150 000 volts, and could be graduated from zero to the pressure required within certain limits. The resistance of the transformer was kept low, so that as large a proportion of energy as possible might be expended on the organic tissue when in short circuit. The primary coil was supplied by six accumulators. A manual rheotome was used so that the operator had perfect control over his instrument. Freshly killed beef was chosen as the best organic tissue upon which to try the discharges, because its structure would easily show any alterations that might take place, and it could be obtained in sufficient mass to allow the current to diffuse. Great difficulty was experienced in cutting sections from the beef after the current had passed through it. Even when frozen or mounted in paraffin it crumbled away into débris. By lowering the pressure in the transformer some sections were obtained and the muscular fibres were found to be broken up throughout the path of the

current. (This was well illustrated by magic lantern slides and micro-photographs.) The destruction was found to extend throughout the path of the current, and was not confined to the poles like the constant current. The sections showed no evidence of heat or caustic action. Some experiments were then tried with an air gap in the circuit, instead of connecting the beef directly to the transformer. The destruction was nothing like so great, probably on account of the high resistance of the air gap. The diffusion of the current was then worked out as nearly as possible by cutting sections from different parts of a thick piece of beef after the passage of the electricity. The area broken up was found to correspond very nearly to the shape of an elliptic spindle. When the poles were not always placed at the same distance apart it was necessary to know the proportion between solid elliptic spindles of different sizes. With the poles six inches apart the solid contents were twenty-seven times greater than at two inches, consequently a corresponding increase or decrease must be made in the pressure of the current or the number of interruptions according as the needle points were moved further apart or brought nearer together. Finally, a Leyden jar acting as a condenser was then introduced into the circuit. The character of the discharge was altered. It took place with far greater rapidity. The maximum pressure was lowered to about 20 000 volts, with a corresponding increase in quantity. The sections taken showed an utter destruction of the beef. Apparently very little diffusion occurred; the discharge made only a narrow lane from one pole to the other. Dr. Parsons gave some demonstrations illustrating the paper.

Dr. LEWIS JONES said that he had made similar experiments on the disintegration of tissue by means of high tension discharges, using a transformer. He was astonished that Dr. Parsons should speak of the destruction of tissue as being produced by the "force of impact," such an expression being vague and meaningless. The destruction of the flesh was due simply to the heat produced by the discharge; indeed, there was no other possible way in which the electrical energy could expend itself on such a conductor as a piece of flesh. In his (Dr. Lewis Jones's) experiments the piece of meat quickly became heated, and if the operation was continued it soon emitted steam and smoke, and finally flame. To say that there was no heat because a thin platinum wire was not heated by the coil discharge was most misleading. Of course, under the conditions of the experiment shown the platinum wire could not possibly have been heated appreciably. The destruction of tissue was much greater round the poles than in the interpolar area, and this point should have been mentioned more clearly by Dr. Parsons.

Dr. HORROCKS said that if it could be shown that living cells, either normal or pathogenic, could be broken up by an electric current, then it was conceivable that this method had a future before it. It had long been known that a simple fracture of a bone united aseptically. Similarly, if one could break up the tissue of, say, a tumour or an inflammatory mass by electrical currents one might succeed in setting up changes which would result in the absorption of the tumour or the exudation. He (Dr. Horrocks) drew attention to the kind of current employed—namely, the faradaic or induced. He could not quite understand how Dr. Parsons had arrived at the conclusion that none of the effects produced were the result of heat. Certainly the sparks shown that evening were very much like lightning flashes, and it was a well-known observation that in death from lightning there was evidence of the effect of heat, especially at the entrance and exit of the electrical fluid.

Dr. ROUTH said that Dr. Parsons had shown how completely the interrupted current could destroy tissues. He asked whether Dr. Parsons was acquainted with the experiments of Sir Benjamin Ward Richardson, which showed that simple non-electrical vibrations changed and reconstructed tissues in various ways. The experiments alluded to were performed on blood taken from the finger, and the products after the shock examined under the microscope. It should not be forgotten that the action of the interrupted current might be influenced in some instances by a neighbouring vibratory wave, and the results be modified.

Dr. PARSONS replied.

The following specimens were exhibited:—

Dr. LEWERS: Tubal Mole removed by Abdominal Section.

Dr. ROBERT WISE: A Couch Table.

Dr. MACNAUGHTON JONES: Uterine Polyp, Vaginal and Uterine Insufflator, and Vaginal and Uterine Stem.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Ruptured Tubal Gestation.—Enteric Fever complicated by Phlebitis and Pleuro-pneumonia.—Traumatic Gluteal Aneurysm.—Exhibition of Cases and Specimens.

A MEETING of this society was held on March 1st, Dr. J. E. EDDISON being in the chair.

Dr. HELLIER showed Marchand's Lacto-butyrometer. This is a quick and simple means of estimating the amount of fat in breast milk. The process consists essentially in dissolving the fat with ether and then throwing it out by admixture with absolute alcohol. The specific gravity of the milk is also taken. In good milk the specific gravity and fat percentage are correspondingly high, but when the specific gravity is high and the fat percentage low infants will not thrive well upon it, and the milk must be looked upon as abnormal.

Mr. W. A. STOTT read a paper on a case of Ruptured Tubal Gestation. Special mention was made of an anomalous sign which was elicited about twenty-four hours after the rupture and which gave rise to an appearance of perforated gastric or duodenal ulcer. The patient was thirteen weeks pregnant, and her symptoms of severe peritoneal hæmorrhage followed immediately an act of micturition. When first seen, nine hours after the onset, everything pointed to ruptured tube, although retroversion and fixation of the uterus, together with great thickness and rigidity of the abdominal walls, prevented a satisfactory bimanual examination. Fifteen hours later it was found that the liver dullness had vanished. In addition all pain had become localised over the stomach and was rendered intense by anything swallowed. Pain had entirely left the pelvic region, and slight abdominal distension had come on. So soon as permission could be obtained the abdomen was opened, twenty-seven hours after onset. The plan intended was to make two incisions: (a) a median hypogastric one, to allow of free washing out from above and then to be used for draining, and (b) an epigastric incision to deal with the stomach lesion. The first-mentioned incision was made, and exploration proved the absence of free gas or food in the peritoneum and the correctness of the original diagnosis. The left Fallopian tube and nearly three pints of blood were removed. The middle portion of the tube was distended and showed a large T-shaped rent. The patient made a rapid and perfect recovery.—The paper was discussed by Dr. Hellier, Dr. Kilner Clarke, Dr. Churton, Mr. Littlewood, Mr. Croft, Dr. Eddison, and Dr. Griffith.

Dr. CHURTON read notes of a case of Enteric Fever complicated by Phlebitis and Pleuro-pneumonia, and followed by Tonsillitis and Peripheral Neuritis. A stout but not very strong girl aged twenty-four was ailing on Sept. 20th, 1894, but continued at work for eight days. On Sept. 29th the temperature was 105° F., pulse 108, respiration 32; a dusky flush on face; diarrhoea; the colon, dull and apparently full, was washed out with warm water. For a week the temperature varied from 103° to 105°.—Oct. 6th: Swelling of right leg; tenderness over popliteal vein. Dulness over lower lobe of right lung; pulse 120, respiration 44; motions still rather frequent and offensive; colon resonant. Salol, ten grains, every six hours.—10th: No diarrhoea; salol omitted; after this date there was constipation.—15th: Signs of pleurisy and pneumonia in left lower lobe.—22nd: Friction sound over right lower lobe, with pain relieved by dry cupping and small doses of morphia. The temperature was normal on Nov. 1st. A week later strict milk diet was stopped.—13th: Sore-throat after chill from an open window; pyrexia for four days.—19th: Pain in right leg, gradually increasing for a week, then "pins and needles" in the toes, chiefly in fourth and fifth; numbness and aching in leg and ankle; nerves tender. The neuritis lasted six weeks. The patient was very sensitive to cold and attributed each additional disorder to a definite chill—turning upon cold sheet and mackintosh after being washed; draught from a window; cooling of room in early morning for stove-cleaning &c.; application of methylated spirit to the back. No antipyrin or cold sponging or baths were used. Quinine, ten grains, was given once; calomel, half a grain, several times. The intestines were cleared as far as possible of "culture media" and kept clear. The case looked serious from the first, and complications began early. The source of the fever could not be found. A nurse attending this patient, after slight malaise for a week or two, was decidedly ailing

on Nov. 28th; went off duty on Dec. 2nd; next day had temperature 105°, with delirium and signs of pleuro-pneumonia in right lower lobe; rose spots in second week; troublesome constipation possibly the cause of a relapse from Dec. 19th to 31st, with renewal of pleurisy; convalescent on Jan. 27th, 1895. She had tepid sponging once, but afterwards declined it when offered.—The paper was discussed by Dr. Eddison, Dr. Solly, Dr. Kilner Clarke, Dr. Chadwick, Mr. Brown, and Mr. Hartley.

Mr. W. H. BROWN read notes of a case of Traumatic Gluteal Aneurysm treated by the old operation of turning out the clots and sac and ligaturing both openings of the vessel. He drew attention to the small number of recorded cases, to the advantages of a very free incision, and to the absolute necessity of a trustworthy surface marking in this case, that of Lizar's having been used.

Mr. ATKINSON related the case of a corpulent middle-aged man admitted under him some years ago with a large Hæmatoma of the Buttock caused by a blow. Three weeks' rest in bed with evaporating lotions reduced the swelling so much that, at his request, he was allowed to go home, but returned next day with a tumour larger than ever. Rupture of the gluteal artery being diagnosed, a long incision was made over the swelling, the clots turned out, and the torn vessel found; this was with difficulty ligatured.—Dr. EDDISON referred to Syme's classical case of gluteal aneurysm. He was present at the operation.

The following cases, pathological specimens, &c., were shown:—

Dr. GORDON SHARP: Upper Jaw from a case of Chronic Glanders.

Dr. CHURTON: (1) Case of hemiplegia from Thrombosis of Middle Cerebral Artery, subsequent Neuritis in Cervical and Brachial Nerves; (2) Patient with Two Abdominal Tumours—(a) Movable Right Kidney and (b) Pyloric Cicatricial Growth.

Mr. W. H. BROWN: (1) Case of Supra-pubic Lithotomy in Adult in which Bladder was sutured; (2) Calculus removed from the Urethra behind a Stricture.

Mr. HARTLEY: Congenital Dislocation of Radius (patient, cast, and photographs).

Mr. LEE WELLS and Dr. T. WARDROP GRIFFITH: Muscular Atrophy after Injury. (The patient has a symmetrical abnormality of the muscles of the arm.)

Mr. LITTLEWOOD: (1) Epithelioma arising in Sebaceous Cyst; (2) Destructive Arthritis of Ankle-joint removed from a Woman aged fifty-six; (3) Hydrocele of Cord removed from a boy.

Dr. T. WARDROP GRIFFITH: Case of Raynaud's Disease affecting the Ears.

Mr. MAYO ROBSON: Case of Pyloroplasty.

MEDICO-PSYCHOLOGICAL ASSOCIATION.

A Review of the last Twenty Years at the Worcester County and City Lunatic Asylum.—Atrophy and Sclerosis of the Cerebellum.—Influenza as a Factor in the Increase of Insanity in Ireland.

A GENERAL MEETING of this association was held at the Powick Asylum, near Worcester, on Feb. 21st, under the presidency of Mr. CONOLLY NORMAN.

The proceedings commenced with an address delivered by Dr. COOKE, medical superintendent, entitled "A Review of the last Twenty Years at the Worcester County and City Lunatic Asylum, with some conclusions derived therefrom." After briefly describing the asylum in the year 1875, Dr. Cooke indicated the additions and alterations that had been made in the accommodation provided for the patients, and the improvements that had taken place in the sanitary and heating arrangements since that date. During the period under review there had been an increase in the number of the patients, due partly to an addition to the population, partly to a decreasing death-rate, and partly to the fact that a number of imbeciles formerly kept in the workhouse are now sent to the asylum. Everything possible had been done to ameliorate the condition of the patients and to promote their cure, and by more systematic training and in various other ways every effort had been made to render the nurses and attendants fully capable of discharging the important duties imposed upon them.—A discussion followed, which was entered into by the President, Dr. Nicolson, Dr. White, Dr. Spence,

Mr. Whitcombe, Dr. Fletcher Beach, Mr. Brinton (member of committee), and others.

Dr. BOND read a paper on Atrophy and Sclerosis of the Cerebellum. An account was given of the clinical history and post-mortem appearances of a well-marked case occurring at the Banstead Asylum. The chief features of the case were the long duration (marked ataxia had been noticed for fifty-three years—i.e., since the age of seven), the practically total destruction of the organ by conversion into fibrous tissue, and the fact that during life very pronounced mental deficiency had existed, at least from the age of seven years, though at death but little cerebral atrophy was found. Allusion was made to several other published cases of cerebellar disease, and by a comparison of them certain deductions were attempted. The microscopical appearances were illustrated by a photo-micrograph.—Dr. Bond's paper was discussed by the President, Dr. Cowan, and Dr. Fletcher Beach.

The General Secretary then read for Mr. McCLAUGHRY a paper entitled "Influenza as a Factor in the Increase of Insanity in Ireland." He first gave a history of influenza, in which he showed that it was known and written on as far back as the fourteenth century, and was first mentioned by Hippocrates. Passing on to the present day, he said we find that the etiology of the disease has for the past two years absorbed the attention of eminent medical men, and, according to the report of Drs. Parsons and Klein to the Local Government Board, there seems no doubt as to the influence of a bacillus which causes the disease. Mr. McClaghry had addressed a series of questions to the medical superintendents of the various asylums in Ireland, and he analysed and made remarks upon their replies. It seems that in forty-nine cases the apparent cause of insanity was influenza, and that the most common type of the former disease was melancholia. Although most of the medical superintendents did not believe that insanity was directly or indirectly due to the disease, he thought that, taking the aggregate number of cases admitted during one year into the twenty asylums from which he had received replies, influenza was as powerful a cause as tea drinking, tobacco smoking in youth, and ether drinking, all of which have been assigned as potent factors in the increase of insanity in Ireland.—A discussion followed in which the President, Dr. Cooke, Dr. Fletcher Beach, and Dr. Seymour Tuke took part.

MIDLAND MEDICAL SOCIETY.

Exhibition of Cases and Specimens.—Etiology of Tumours.

An ordinary meeting of this society was held on March 6th, Mr. T. F. CHAVASSE, President, being in the chair.

The PRESIDENT showed a Uterine Myoma weighing nine pounds which he had removed by abdominal section from an unmarried woman aged thirty-five years. The history of growth extended back four years. Numerous adhesions existed, and the pedicle, which was broad, was treated extra-peritoneally by a wire constrictor. Recovery was uninterrupted.

Mr. GEORGE HEATON showed a boy aged twelve years with a large Valvular Growth growing from his left false cord and causing much inspiratory dyspnoea. In addition to the main growth there were several smaller ones growing from the mucous membrane on the inter-arytenoid space. The boy had suffered from frequently recurring attacks of croup, and a year previously had had tracheotomy performed for laryngeal obstruction, and wore a tube twelve days. Mr. Heaton proposed to remove the growths by laryngotomy, and gave his reasons for preferring this method.

Dr. FOXWELL exhibited a man with a New Growth originating in the Posterior Mediastinum, which had compressed the main bronchus of the right lung and also that supplying the lowest lobe. The superficial veins of the lower half of the thorax were dilated, especially on the left side (probably from pressure on the smaller azygos as it crosses the spine to join the larger). There was also a large mass of glands in the right supra-clavicular fossa. The first symptom of ill health was noticed at the end of November, 1894.—Dr. FOXWELL also showed a boy aged three with a large Liver of very dense consistence, which he considered to be Cirrhotic owing to alcohol, with which he had been regularly dosed by his parents.

Dr. MORRIS showed a Brain from a case of Cerebral Hæmorrhage. A large hæmorrhage in the left hemisphere

had burst into the lateral ventricle and passed downwards into the medulla. The symptoms were apoplexy, slight rigidity of all the limbs with occasional unconscious movements, no strabismus, facial muscles equally inactive, inability to swallow, Cheyne-Stokes respiration, equally contracted pupils, polyuria, and glycosuria. The case was first diagnosed as diabetic coma, and subsequently as hæmorrhage into the pons or medulla.

Dr. LESLIE PHILLIPS showed three patients—(1) a case of Chronic Pemphigus of eight months' duration noteworthy from the very small size of the great majority of its bullæ; (2) a case of Phagedænic Ulceration of the Penis in course of repair after the free application of the Paquelin cautery; and (3) a man discharged from the army in India on account of Syphilis. One side of the nose had been lost nineteen months after the primary sore, and much destructive ulceration had attacked the lesions in other parts of the skin. Dr. Phillips directed attention to the occurrence in his practice at the present time of many cases of syphilis of a severe and intractable type.

Mr. CHRISTOPHER MARTIN showed a Sarcoma of the Ovary removed successfully from a woman.

Dr. O. J. KAUFFMANN then read a paper on the Etiology of Tumours.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

Exhibition of Cases.—Treatment of Suppuration in certain Osseous Cavities.

THE eighth meeting of the seventy-fourth session of this society was held on March 6th, Mr. JOSEPH BELL, Vice-President, being in the chair.

Dr. A. L. GILLESPIE showed three patients: (1) a young man with Deformity of Both Hands, only the thumb and two fingers being present; (2) two sisters with Goitre and Rapid Pulse in whom marked improvement had taken place under the administration of bromide and iodide of strontium; and (3) a child with Persistence of the Anterior Fontanelle. Dr. Gillespie also gave an exhibition of Lip-reading in the Deaf and Dumb.

Dr. NORMAN WALKER showed a peculiar case of Eczema exhibiting a Linear Eruption, which had commenced on the wrist and extended up the arm and down the chest. He also showed a case of Lichen Spinulosus.

Dr. WILLIAM RUSSELL showed: (1) a Malignant Ovarian Tumour; (2) the Lungs from two fatal cases of Influenza Pneumonia; (3) an Aneurysm of the Abdominal Aorta; and (4) an Impacted Gall-stone, the gall-bladder having been tacked to the hepatic flexure of the colon and the abdominal wall, and so rendered functionless.

Dr. LEITH showed: (1) a Pancreas with Abscesses in the head, tail, and body; there were impacted gall-stones in the bile-duct; and (2) photographs of an Aneurysm opening into the Superior Vena Cava.

Dr. McBRIDE read a paper on some questions with regard to the Diagnosis, Prognosis, and Treatment of Suppuration in certain Osseous Cavities. He divided his subject into—(1) suppuration of the middle ear; and (2) suppuration of the nasal accessory cavities. 1. In suppurative ear disease, more particularly when chronic, the great desideratum was free drainage. He first sketched the various operative methods for gaining access to the middle-ear cavities. Recent cases of middle-ear suppuration where no great amount of destruction of the drum had taken place were usually curable with Schwartz's operation alone. It was a question, therefore, whether in subacute cases threatening to become chronic the mastoid antrum should not be opened more frequently than was at present customary. In chronic cases it was rare to get a cure. It was recommended by surgeons to drain through the mastoid in cases of chronic suppuration which had resisted treatment for a year. His own experience had made him an opponent to this view. 2. Suppuration of the nasal accessory cavities. If in a patient we had arrived at the conclusion that the antrum, anterior ethmoidal cells or frontal sinus were at fault it was usual to suspect the antrum first, and by various methods—e.g., posture, transillumination, introduction of a tube into the natural opening, and exploration—we could determine whether or not it contained pus. If it did not we were driven to the conclusion that either the anterior ethmoidal cells or the frontal sinus gave origin to the discharge. He thought it doubtful if even the most skilled rhinologist in

that case could do more than express an opinion and explore. Having sketched the treatment of such a case he dwelt on the difficulty of diagnosing suppuration of the frontal cavity. In empyema of the posterior ethmoidal cells and sphenoidal sinus diagnosis became still more difficult. In treatment of empyema of the antrum a great deal depended on the duration of the affection. Opinion was generally in favour of making an artificial opening. In recent cases it was best to open through the socket of a tooth. In chronic cases, where drainage was required for months or years, opening through the alveolus was best. He deprecated opening through the meatus as the orifice was difficult to maintain. In cases which resisted all other efforts Jansen's operation might be employed. In view of the extreme obstinacy of these antral cases if allowed to remain for years, he thought they ought to be opened early, when the extraction of a tooth and the introduction of a vulcanite plug with regular washing would effect a speedy cure.—Mr. JOSEPH BELL quite agreed that they should not be in too great a hurry to open the antrum in chronic middle-ear suppuration, especially in children. With reference to the different methods of operation, he thought the great thing was to get into the antrum and then work one's way upwards and backwards, cutting away all the softened bone and not removing more healthy bone than was necessary.—Dr. MACKENZIE JOHNSTON thought cases of middle-ear suppuration would undoubtedly benefit by opening, but he thought patients would not submit to the operation till the surgeon was prepared to say that it was necessary. At present they were not in a position to say whether a case should or should not be operated upon simply because the discharge did not stop in twelve months. When a case lasted longer were they to operate or await symptoms? He would rather open at the earlier stage if one could get the sanction of the patient and the practitioner.—After some remarks by Mr. WALLACE, Dr. MCBRIDE replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

Intra-ligamentous Cyst.—Ovary and Tube removed for Pyosalpinx.—Leucorrhœa: its Causes, Varieties, and Treatment.

A MEETING of this Section was held on March 1st, Dr. R. D. PUREFOY, President, being in the chair.

Dr. SCOTT said: "The specimen of Intra-ligamentous Cyst described by Dr. Macan at a former meeting was placed in my hands by the Reference Committee for examination. It consists of the greater portion of the uterus and the appendages of both sides. In the cervical portion of the uterus I found the cavity to be one inch deep, while the body contained three myomata about one and a quarter to one and a half inches in diameter and some about half an inch in diameter or less. The total uterine mass measured about four inches antero-posteriorly and about two inches laterally. The Fallopian tube on the left side measured about three inches, and with the ovary was apparently normal. On the right side the broad ligament was distended by a large sac measuring about four and a half inches antero-posteriorly and about six inches laterally. The Fallopian tube was stretched by the cyst until it measured eight inches, and was so very closely incorporated with the cyst wall at its uterine end that microscopical sections had to be made to trace its position. The right ovary was rather smaller and more elongated than the left. The ovary and Fallopian tube lay at opposite sides of the sac. The position of the sac in the broad ligament, filling up the space between, and attached to both the ovary and Fallopian tube and its epithelial lining, would point to an origin from the remains of that part of the Wolffian body known as the parovarium, or from the small portion of the Wolffian duct which is sometimes attached to the tubular portion of the parovarium."

Dr. F. W. KIDD exhibited an Ovary and Tube removed for Pyosalpinx. One week after operation the stitches were removed, and there was perfect union of the abdominal incision.

Dr. MORE MADDEN said that the subject of Leucorrhœa is deserving of fuller consideration than is generally accorded to it. The term should be restricted to such non-hæmorrhagic or mucoid discharges from any portion of the genital lining

membrane as contain morphological or other elements foreign to healthy mucus, and are of pathological significance. Vulvar leucorrhœa is most frequently brought under notice in pædiatric practice, and more usually is of constitutional or strumous origin, although it not infrequently arises from topical causes, whether catarrhal, or simple inflammatory, traumatic, or specifically infective, such as gonorrhœa. Vaginal leucorrhœa may be caused either by any of the local exciting causes of genital hyperæmia or by any abnormal constitutional condition by which the tenuity of the vaginal vessels is so impaired as to give rise to non-hæmorrhagic exudation therefrom. The most common of the former causes are catarrhal and simple inflammatory vaginitis; and next in frequency is gonorrhœal infection. The distinction between these is generally a matter of difficulty and is often an impossibility in actual practice; in many instances the physician must rely more on the history, symptoms, and probabilities of the case than on any differentiation from the readily ascertainable presence or absence of gonococci in the discharge. Whether specifically infective or not, however, the treatment of these cases is practically identical. In either instance the primary object should be to secure as far as possible the asepsis of the affected parts by the free use of warm antiseptic injections, such as lysol or boric acid (1 in 25), or corrosive sublimate (1 in 2000), so as to sterilise and cleanse the vaginal surface from the discharge which, even if not specifically infective, when allowed to accumulate or decompose must act as a direct source of irritation, as well as a possible nidus for pathogenic micro-organisms by which the entire genital tract may be infected. In the second place, the same indications may be carried out most effectually immediately after each douching by vaginal insufflations of loletin, salol, or boric acid powder, or so-called "dry treatment." For the relief of pruritus of the pudendum Dr. Madden suggested the application of the methylene blue lotion, which he has recently recommended as one of the best of all local analgesics in pruritic affections generally. Cervical leucorrhœa is very frequently of special importance in connexion with the causation of obstructive dysmenorrhœa and sterility, in which cases the cervical canal may be so sealed by an abnormally viscid and hyper-alkaline exudation from the Nabothian follicles and cervical endometrium as to interpose mechanical obstacles to either menstruation or conception. In the local treatment of such cases chief reliance should be placed on the free use of the cervical curette, before which Dr. Madden recommends the thorough dilatation of the canal by means of his rapid dilator, and immediately after curetting he applies iodised phenol or salol bougies to the affected surfaces.—Dr. TWEED thought that leucorrhœa was a symptom of almost every disease of gynecology. He wanted to know some diagnostic difference between simple vaginitis and that due to gonorrhœa. For some time he had been using the microscope to distinguish between them, but was sorry to see that Dr. Madden threw some doubt on the bacteriological examination. He placed a little of the pus on a slide, pressed out with a cover-glass, removed the latter, and applied an aqueous solution of methyl violet. In a few minutes he washed it with water and replaced the cover-glass. The whole thing did not take more than two minutes.—Dr. ALFRED SCOTT said that if the pus was stained with methyl violet it was almost impossible to miss the micrococci. Unfortunately, there were about eight micrococci which belonged to the same class. The most convenient check was to stain by Gram's method. If they stain by this method they are not gonococci. Cultivation was much more difficult, and took from one to two months.—Dr. MORE MADDEN, replying, said that he was glad his paper had given rise to so much discussion, but doubted the ready diagnosis of gonorrhœal from ordinary leucorrhœa by the immediate recognition of the gonococcus.

YORK COUNTY HOSPITAL.—The annual meeting of the York County Hospital was held on March 12th. The Dean of York presided, and the 154th annual report was presented. The income of the hospital has suffered considerably through the depression in trade, but an increase of £31 in the workmen's collections was commented on with satisfaction. The Earl of Faversham contributed £250, which was employed in laying out the grounds in the rear of the hospital, where a very pleasing ornamental effect has been produced by planting evergreens and forming grass plots.

Reviews and Notices of Books.

Physiologie. Travaux du Laboratoire de M. CHARLES RICHEL.
Tome III. Avec 25 figures dans le texte. Paris: Félix Alcan. 1895. Pp. 577.

THIS volume embraces, amongst numerous others, the following subjects: 1. Chloralosis. 2. Serotherapeutics. 3. Tuberculosis. 4. Defences of the Organism. Chloralose is the body which results from the action of anhydrous chloral on glycose. It is crystallisable, being soluble in boiling water from which it is deposited in crystals on cooling. It has a disagreeable taste. In dogs, in doses of about three grains per pound weight of the animal, it has little action for about three-quarters of an hour. The muscles then appear to become rigid, with fibrillar contractions, and the movements become slow; intelligence is preserved, but there is somnolence; the animal lies down and the eyelids tend to close; there is at the same time an increase of reflex excitability, the animal trembling at the slightest sound. The movements of the heart and respiration are unaffected. At the expiration of an hour and a half sleep is profound, but the excitability is greatly augmented. The slightest touch causes almost a tetanic convulsion. The sleep, therefore, differs from that produced by morphia because the animal does not dream, and from that of chloral because the spinal cord is wide awake when the brain slumbers. It has been employed by M. Ch. Féré in cases of epilepsy, hysteria, and chorea. Another paper, by MM. J. Héricourt and Charles Richet, deals with Transfusion of the Blood of the Dog into the Peritoneal Cavity of the Rabbit. It is very remarkable that the injection of twelve cubic centimetres of the blood into the veins of a rabbit will cause its death in a few minutes, whilst it will readily bear the injection of 120 cubic centimetres into the peritoneum. After such an injection the animal crouches on its belly, and usually soon passes a large quantity of limpid urine. The temperature falls, and in the course of a week's time there is a notable loss of weight. An important point was also noticed—namely, that after the injection the virulence of the staphylococcus septicus was greatly diminished when the animal was infected with it, the blood of the dog absorbed by the rabbit appearing to possess the power of resisting the pathological influence of the staphylococcus. Guinea-pigs are more easily poisoned by the transfusion of dog's blood than rabbits. The introduction of twenty-five grammes of dog's blood per kilogramme was almost certainly fatal. The blood of the duck is even more poisonous than that of the dog; in the case of the rabbit seven grammes appear to be a toxic dose. A single gramme of the blood of the eel will kill a vigorous rabbit in the course of a few minutes, but a rabbit survived after the injection of five grammes of the blood of a carp. The authors of the paper have satisfied themselves that the injection of the blood of the dog into the rabbit, whether into the blood or into the peritoneum, retards the supervention of tuberculosis under conditions in which it would otherwise take place.

M. Richet has an interesting article on Functions of Defence in Man and Animals, dealing, amongst other things, with the power warm-blooded animals have of resisting exposure to cold. In the dog exposure to a cold of -91°C . for half an hour was accompanied by a rise in the rectal temperature, and it resisted the effects of that degree of cold for two hours. Shivering on exposure to cold may be contrasted, he remarks, with the beneficial effects of sweating on exposure to heat. He points out the advantages of the sentiment of fear which is inspired by so many animals and circumstances, and which saves us often from ourselves. The same may be said of the feeling of vertigo. M. Richet maintains that were it not for the sensation of

vertigo falls and serious accident would be of much more frequent occurrence. Pain, too, or the anticipation of it, has its protective influence. Under pain the respiration quickens, the heart beats more rapidly, the arterial blood pressure rises, the glands secrete more abundantly—all conditions that tend to the reinforcement of the biological activity of the organism. As Brown-Séquard would have said, there is dynamogeny of the whole body. Finally, he considers the remarkable means of defence we possess in our leucocytes and phagocytes against the multiplication of microbes in our system. The volume contains several other valuable articles.

LIBRARY TABLE.

Elements of Surgical Pathology. By AUGUSTUS J. PEPPER, M.S., M.B. Fourth Edition. London: Cassell and Co. 1894.—In a notice of the first edition of this book we expressed the opinion that it supplied a real want and supplied it well; and though in the twelve years that have elapsed since then great advances have been made in surgical pathology, we cannot but acknowledge that the work before us is still fully worthy of being recommended to the student as a trustworthy guide to the subject of which it treats. The present issue has been brought up to date, the original text having been entirely rewritten, and several new subjects being treated which were unnoticed in former editions. The book is remarkably free from mistakes of all kinds, but occasionally we find a sentence in which an alteration is desirable. The illustrations are numerous and good. Altogether the book is a worthy member of the excellent series of student's manuals to which it belongs.

Atlas of the Human Brain and the Course of the Nerve Fibres. By EDWARD FLATAU. Translated by WM. NATHAN and JOHN H. CARSLAW. Berlin: J. Karger. Glasgow: F. Bauermeister. 1894.—It is a difficult thing adequately to appreciate such a work as this. The result in the actual number of plates of what must have been a very great expenditure of time and care and industry may seem to be small, yet in this atlas we have presented to us all the important aspects of the brain in a sufficient series of the most beautifully executed plates. If anything can be substituted for the actual brain in the course of anatomical study, we should imagine that such plates as these could, and in one particular this atlas is peculiarly valuable—viz., the diagram which is given of the course of the nerves and tracts in the spinal cord. A short but sufficient explanatory text is furnished, and we congratulate the author on the completion of a work upon which he must have spent much pleasant labour, and the translators on the enterprise which has led them to render the atlas available to English students.

Diphtheria and its Successful Treatment. By BROWNLOW R. MARTIN, M.B. Dub., L.R.C.S. Irel. Second Edition. London: Baillière, Tindall, and Cox. 1895.—This little work of sixty-four pages is essentially an earnest recommendation of sulphite of magnesium as a reliable agent in the treatment of diphtheria. This sparingly soluble salt is to be applied locally by free insufflation, so that "about the sixteenth part of an inch deep of powder should be dusted all over the surface of the mucous membrane wherever the diffuse redness extends." At the same time, tabloids containing each five grains of the salt are to be sucked constantly, and perchloride of iron is to be administered, either alone or in conjunction with chlorate of potassium. The author records numerous cases, both in his own practice and in that of others, in which this treatment has been attended with success.

The Phonographic Record of Clinical Teaching and Medical Science. No. 4. London: Sir I. Pitman and Sons.—In accordance with an announcement already made the scope

of this publication has been widened, and the current number, in addition to two short clinical lectures, contains articles on the Use of Digitalis, by Dr. James Little, and on the Quenching of Thirst by the Use of Enemata, by Mr. C. W. Cathcart, F.R.C.S. The clinical lectures, which deal with the Backward Displacement of the Gravid Uterus, and with Chancres in Women, are respectively by Dr. Thomas Wilson and Prof. H. R. Spencer. We are pleased to note that the "Evercirculators," to which we referred last month, have commenced, and they should prove of great educational value to the members of the Society of Medical Phonographers, of which the "Record" is the official organ.

Respiration in Singing. By Dr. JOAL. Translated by R. NORRIS WOLFENDEN, M.D. London: F. J. Rebman. 1895.—This little work, although intended primarily for singers, contains many observations on respiration which are of interest both to the physiologist and the physician. The object of the book is to advocate the importance of costal respiration and its superiority over purely diaphragmatic respiration for ordinary purposes, and especially for the production of voice by singers. Dr. Joal makes out a strong case, but both the body of the work and the translator's preface are disfigured by the introduction of personal controversy.

Analytical Records

FROM

THE LANCET LABORATORY.

WYETH'S WINE OF TAR.

(JOHN WYETH AND BROTHER, PHILADELPHIA, AND W. F. HORTON, 30, SNOW-HILL, E.C.)

THE method adopted for the manufacture of this preparation is interesting. A solution containing malt and hops and a small quantity of honey is first made, which is then allowed to ferment for from four to six weeks at between 98° and 100° F. in the presence of tar specially selected for the purpose. When alcohol has been produced to the extent of between 7 and 8 per cent. the liquid is filtered and bottled. It is a dark-brown, alcoholic solution, possessing a not unpleasant smell and taste referable to tar constituents. It is said to be useful in bronchial and gastric catarrh, moderating the cough and promoting expectoration. Wyeth's wine of tar is certainly an advance on ordinary tar-water, which is unreliable, because very variable in composition, while it would appear that by the adoption of fermentation and subsequent filtration in the course of its preparation the irritating and acrid principles commonly present in tar, and which are to be found in the ordinary aqueous extract, are excluded. In addition, it obviously possesses nutritive properties, since it is in part prepared on the same lines as beer.

VARIOUS COMPRESSED TABLETS.

(PARKE, DAVIS, & CO., DETROIT, MICHIGAN, AND 451, OXFORD-STREET, LONDON, W.)

A useful series of compressed drugs, based upon more or less novel formulæ, which are worthy the attention of the profession, has recently been submitted to us by these enterprising pharmacists. We have subjected most of them to careful analysis, and in nearly all cases we have succeeded in getting reactions in response to the presence—although in some cases quite minute—of the various medicaments contained in them. Thus the saline and chalybeate tonic tablets are of somewhat complex composition, but we obtained distinct evidence of each constituent. The formula (after Dr. Flint) is as follows: sodium chloride, 3 grains; potassium chloride, 32 grains; potassium sulphate, 1·10 grains; potassium carbonate, 1·20 grains; sodium carbonate,

3·5 grains; magnesium carbonate, 1·2 grains; calcium phosphate, 1·2 grains; iron reduced by hydrogen, 9·20 grains; and carbonate of iron, 1·20 grains. That the reduced iron was present as such was proved by the fact that the residue left undissolved by water evolved hydrogen on the addition of dilute sulphuric acid. Of other compressed tablets the following appear to be worthy of mention: trifolium comp. (alterative), containing the extracts of red clover, stillingia, xanthoxylum, lappa, phytolacca root, and iris; acetanilide comp., containing acetanilide in conjunction with camphor monobrom., and citrate of caffeine; ergotin comp., composed of ergotin (Bonjean), tinct. foxglove and quinine sulph.; compressed tablets (anodyne) composed of camphor ext. henbane, morph. acetate, and capsicum; cubeb tablets, containing besides powdered cubebs, sulphate of iron, copaiba, Venice turpentine, sandalwood oil, and oil of wintergreen; tablets of Dover's powder; compressed tablets (chlorodyne) consisting of morph. hydrochlor., ext. cannab. Indica, nitro-glycerine, ext. hyoscyamus, and oleoresin capsicum; aphrodisiac tablets, composed of ext. damiana, nux vomica, zinc phosphide, and cantharides; tablets containing equal amounts of the bromides of sodium, potassium, and ammonium; and lastly, tablets (damiana comp.) composed of ext. damiana, phosphorus, and ext. nux vomica. They all serve as excellent illustrations of progressive pharmacy.

AUSTRALIAN BRANDY.

(JOSHUA BRUCE, MELBOURNE. LONDON OFFICE: 26, MARK-LANE, E.C.)

An analytical notice of this interesting and important colonial product appeared in THE LANCET of July 2nd, 1892, since which, however, we learn that it has been considerably improved; while in order to further guarantee its genuineness it is now being bottled in London under the personal supervision of the above firm. We have submitted a new sample to examination, with the result that, although we find a small diminution in the proportion of spirit, yet in every other respect its excellent quality is maintained. It is a pure product, possessing a blandness of flavour, and is well suited for medicinal purposes.

CASCARINE (LEPRINCE) LAXATIVE PILLS.

(MAURICE LEPRINCE, PARIS; LONDON: F. NEWBURY & SONS, 1 & 3, KING EDWARD-STREET, NEWGATE-STREET, E.C.)

The extract of "cascara sagrada" is a well-known valuable addition to modern aperients, but as ordinarily prepared it contains certain constituents which, if not irritating or giving rise to other objectionable results, are at least inert. In the above preparation M. Leprince claims to have separated a distinctly definite chemical product—cascarine—the administration of which secures the beneficial action of the "sacred bark," while it excludes the irritating effects which with some individuals are known to follow the use of this drug. The pills are neatly coated and contain a brown, brittle mass which dissolves completely in water. We find that the claims advanced in regard to their uniformity and ease of action are not without foundation.

MARROL.

(THE LIQUOR CARNIS CO., 28A, FARRINGTON-STREET, E.C., AND ASTON CLINTON, BUCKS.)

This is one of those valuable and interesting preparations belonging to a useful series of foods made by the Liquor Carnis Co., in which the ordinary physical conditions of fat are modified by the peculiar action of the enzyme of malt, by which it is held ready for immediate absorption and appropriation. Thus under the microscope the fat in Marrol, consisting of the yellow marrow of ox bone, appears to exist in true solution, but when a drop of water is added, immediately myriads of tiny fat globules are seen to separate. At the same time, the digestive activity of the diastase is not impaired, since an aqueous solution of Marrol rapidly converts starch into soluble carbohydrates.

According to our analysis the composition of Marrol may be thus represented: moisture (loss at 100° C.), 18.10 per cent.; mineral matter, 2.07 per cent.; fat, 10.43 per cent.; proteids, 2.31 per cent.; malt extractives, sugars, &c., 67.09 per cent. We may regard it broadly, therefore, as consisting of one part of marrow fat held in the state of emulsion by nine parts of pure active malt extract. Both, of course, introduce valuable proteids and mineral constituents into the compound, the former contributing compounds of phosphorus and iron (from the hæmoglobin and the fat of the marrow), and the latter the extracted phosphates of malt. Marrol is, therefore, of peculiar and undoubted value, therapeutically as well as dietetically. An important feature is its attractive flavour, which is partly referable to the delicate bitter of the hop contained in the malt extract.

"FOOTBALL" OATS.

(ROBERTS, SIMPSON & CO., 46, STANLEY-STREET, LIVERPOOL.)

This preparation consists of the berries of the oat rolled and flattened into wafers, by which, doubtless, it is rendered dietetically more acceptable. Prepared in the manner directed, a porridge of rich oaten flavour is obtained. This product is, of course, of the same high nutritive value as the oat itself, the proportion of nitrogenous matters and phosphatic constituents in which is well known to exceed all other cereals.

PILL FERRUGINOUS WITH CASCARA SAGRADA AND NUX VOMICA.

(W. H. SCHIEFFELIN & CO., NEW YORK. POTTER & SACKER, 80, FENCHURCH-STREET, E.C.)

Apart from the excellent formula of these pills they readily break up and diffuse their contents in water at the temperature of the stomach. Each contains sulphate of iron, 2½ grains; carbonate of potash, 2½ grains; extract of cascara, 1 grain; and nux vomica, ¼ grain—a combination which is designed to obviate the constipation associated with anæmic conditions, while securing the beneficial effects of the proto-carbonate of iron, which is formed on the interaction of the carbonate of potash with the proto-sulphate of iron.

MONTE FIANO (ITALIAN WINE).

(AGENTS: MORRISON, POLLEXFEN & BLAIR, 34, LEADENHALL-STREET, E.C.)

This wine is said to be grown under favourable environments both of soil and aspect, which doubtless would account for its freedom from that roughness upon the palate which characterises many Italian wines grown probably under less favourable conditions. As the following analysis indicates, it is a light, sound wine, well adapted for table use: alcohol, by weight 7.93 per cent., by volume 9.86 per cent., equal to 17.29 per cent. proof spirit; extractives, 2.03 per cent.; mineral matter, 0.18 per cent.; total acidity reckoned as tartaric acid, 0.42 per cent.; sugar, 0.10 per cent. Thus it is free from excessive acidity and contains practically no saccharine matters.

WINTER STOUT.

(BRATBY, HINCHCLIFFE & CO., LIMITED, SANDFORD-STREET, GREAT ANCOATS, MANCHESTER.)

This beverage closely resembles stout in appearance and tastes like home-brewed ginger-beer. Ginger, sugar, and a brown colouring agent—possibly derived from burnt malt—are probably, therefore, the chief ingredients of the preparation. On distillation it proved to contain 1.25 per cent. by weight of alcohol, equal to 1.57 per cent. by volume, or 2.75 per cent. proof spirit. In the light of this result it may be regarded as a temperance, and probably wholesome, beverage. It appears, however, to be liable to excessive and persistent frothing, which forms not a small drawback to a drink of this class.

COGNET'S CAPSULES (IODOFORM CREASOTED).

(LONDON AGENCY: ROBERTS & CO., 76, NEW BOND-STREET.)

The excellent formula of the fluid contained in these neat capsules is as follows: absolute eucalyptol, 0.10 gramme; pure creasote, 0.05 gramme; chemically pure iodoform, 0.01 gramme. On immersing a capsule in water at 100° F. the oily contents soon burst through the envelope, imparting the distinctive taste of each medicament to the water. The materials employed are evidently of the purest possible kind. The capsules are recommended in chronic bronchitis, laryngitis, and in other affections of the respiratory tract, as well as in phthisis.

New Inventions.

THE STANDARDISATION OF EUCALYPTUS OIL AND A NEW METHOD FOR THE SEPARATION OF EUCALYPTOL.

OIL OF EUCALYPTUS has of late years come largely into medicinal use, chiefly as an agreeable and effective antiseptic, and its purity is therefore of considerable importance. It is generally admitted that the oil best suited for medicinal purposes is that which contains the highest proportion of eucalyptol, which in genuine eucalyptus oil is the chief constituent. Other oil constituents have been known to be a source of irritation when the oil has been employed for the purposes of inhalation. Hitherto the standardisation and assay of eucalyptus oil have not been placed upon a very satisfactory basis, certain results of greater or less value being afforded by making observation of the boiling point and specific gravity, and by separating the eucalyptol by crystallisation in the cold. These physical methods promise now to be superseded by a well-understood chemical method, which is much more conveniently carried out and which is calculated to give a better estimate of the medicinal worth of the oil. The method alluded to is the precipitation of the eucalyptol in the form of a crystalline phosphate and its consequent complete separation in a pure state from foreign oils. Apart from the value of this discovery in affording a ready means of assaying eucalyptus oil, it enables the preparation of an article containing a perfectly definite and standard amount of true eucalyptol, so that standardised oil of eucalyptus may now be demanded. The process consists of the addition to the essential oil of eucalyptus or other volatile oil containing eucalyptol of a solution of phosphoric acid. For this purpose the oil to be treated should be at an ordinary temperature and not higher than 60° F., and the solution of phosphoric acid is best when it is of a specific gravity of not less than 1.750. The effect of this addition is to produce or precipitate a crystalline compound of "eucalyptol phosphate." The crystalline compound so formed is separated from the other constituents of the oil by any known process—such as pressure or centrifugal action—and the salt is subsequently decomposed by hot water for the production of a fluid absolute eucalyptol, which floats over the phosphoric acid solution and may be separated by decantation. This interesting discovery is due to Mr. L. R. Scammell, a member of the firm of Messrs. F. H. Faulding, of Adelaide and 9, South-street, London, E.C., who are placing standardised oil of eucalyptus on the market. We have recently examined in the Laboratory specimens of pure eucalyptol obtained in the manner indicated, and also a specimen of standardised oil stated to contain 50 per cent. eucalyptol. We found that the latter, when treated with syrupy phosphoric acid, turned into a semi-solid mass of crystals. On pressing the crystals between bibulous paper several times a clean and perfectly white cake of crystals was obtained, which on solution in hot water yielded a volume of eucalyptol exactly equal to a half of the volume of the original oil. This result is in perfect agreement, of course, with the statement that it contains 50 per cent. eucalyptol. Similarly the specimens of pure eucalyptol turned completely solid on stirring strong phosphoric acid with it, which on pressing and drying gave precisely the same volume as the original eucalyptol. The process is evidently a valuable discovery, and there can be little doubt of its importance, since it ensures the production of a pure and reliable agent for all medicinal purposes.

THE LANCET.

LONDON: SATURDAY, MARCH 16, 1895.

THE official roll of the profession, the Medical Register for 1895, is now before us, and calls for some analysis at our hands. We have already congratulated Mr. MILLER, the Registrar, on its early appearance.

The most interesting part of the volume to the profession is Table F., which shows the number of persons whose names were entered in, added to, or removed from the Medical Register, not only during the last year, but during the last twenty years. The names and addresses in the Register are only an approximation to the actual constitution of the profession at any given moment. There are constant sources of error in the migratory habits of a certain proportion of the profession, and in the unreported deaths of others. At special times, when the Registrar has wished to make sure of the accuracy of the addresses by letters of inquiry, five or six hundred of these letters have been returned unopened to the office. In one year no less than 618 names were removed from the Register because the persons whom they represented made no reply to such letters. In the last year this cause of error in the Register has only been ascertained in thirty-three cases, so that the statistics are unusually free from error on this score. There is another source of error which it is found difficult to eliminate—the number of deaths. This very table shows one of two things—either that the deaths in the profession are very inadequately ascertained, or that the members of the profession are getting healthier and less liable to death. All the deaths in 1894 that could be ascertained by the Registrar—and it is known that great pains are taken for this purpose—were 458. The deaths in the previous year were 546. Not only were the deaths during 1894 less by eighty-eight than those in 1893, but the average annual number of deaths of medical men for the last five years is much less than in the preceding five years. For the later period the average annual deaths were 522, whereas for the earlier, and with a smaller profession by thousands, the annual deaths were 582. The mortality of the profession is considered by statisticians to be excessive; it is therefore the more satisfactory to have this evidence that it is diminishing, but we cannot help fearing that a considerable proportion of such deaths are not reported to the Registrar of the General Medical Council. The profession is a scattered one; many of its members practise and die in remote places—on the sea, in colonies, and in foreign countries. We must not flatter ourselves that the 458 deaths in this table represent the total mortality of the profession.

But the most important figures in this table are those which give us the total numbers of the profession and enable us to judge of their tendency to increase or diminish. We may first notice the new names added to the Register. These numbers in recent years have been formidable. In 1887 1531 were added by registration to the profession, in 1892 1513, and in 1893 no less than 1579. In the year 1894,

with which we are now dealing, after the bloated figures of the two previous years, it is a relief to find that there was a fall to 1426 registrations, or 153 less than those of the year before, in which the numbers were the largest on record. To show with what rapidity the numbers of the profession have lately tended to rise, we may say that, whereas the average additions to the Register for the last nineteen years were 1259, for the last five years they have been 1426, which we have seen is exactly the number added in the year 1894. Coming to the total number on the Register for this year, we find it to be 32,637, as against 31,644 for 1893, or an increase of 993. As we have said, this can only be an approximative number, being liable to various errors; but it is doubtless correct enough for all purposes. One proof of this is its close correspondence with the numbers in the Medical Directory obtained by other methods, which are 32,590, or 47 less than those given in the Register.

There is silent evidence even as to character in the figures of this table. A line is given to removals from the Register under the penal clauses of the Medical Act. Twelve removals of this sort are tabulated in 1894, and this is the largest number—twice the average number—in the history of the Council. We have no wish to make light even of such a number; but distributed over 32,637 it is not very serious, amounting to 1 in 2719. In the majority of these the transgressions which led to removal were not such as courts of law would take notice of, but offences under the Medical Act, such as covering, &c. Students of the Medical Register will find much other material of interest in this volume on which we cannot now dwell. Every member of the profession can add to its accuracy and its value by sending the Registrar early information of changes in his own titles or address, or of the death of medical men on the Register.

NUMEROUS as have been the researches on the mechanism of accommodation in the eye, none of the theories that have hitherto been advanced seem to be able to satisfy all the conditions; and from time to time fresh researches are made essaying to afford a solution of physiological or of pathological phenomena not accounted for or not being capable of explanation on existing theories. The most recent investigation and discussion on the subject are to be found in the current number of *Pflüger's Archiv*, from the pen of Dr. WILHELM SCHOEN, who has long been engaged upon it. The physiological problem of accommodation as propounded by AUBERT was: How can the increase in the convexity of the anterior curvature of the lens in accommodation of the eye for near objects take place without change of curvature of the posterior surface of the lens and without change of place of the lens itself? Dr. SCHOEN thinks the question to be solved would be better put in these terms: How can the increased curvature of the anterior lens surface in accommodation of the eye for near objects occur without change of place, without material alteration in the curvature of the posterior surface of the lens, without forward movement of the whole lens, and without increase of tension in the anterior chamber? The first two postulates and the last may be regarded as settled, for that there is no augmentation of tension in the eye as the result of the act of accommodation has been proved in a very practical manner

by FORSTER, who noticed that in a case of conical cornea which had been punctured to allow of the escape of part, but by no means of the whole, of the aqueous humour the cornea became concave on fixing a near object and convex on looking at a remote one. In a second case of perforating ulcer of the cornea, after abscission of the projecting portion of the prolapsed iris the corneal reflection became distinctly larger when near, and smaller when distant, objects were looked at.

The anatomical data given in many text-books are, Dr. SCHOEN thinks, incorrect, but he supports the views of DONDEERS and of HENLE. He holds that the free part of the zonula or wall of the canal of Petit is composed of three fasciculi—an anterior, a middle, and a posterior—which separate from each other just behind the ciliary process. The anterior of these is identical with the anterior wall of the canal of Petit, and extends, forming arches with their concavities looking forwards upon the ciliary processes, to the anterior capsule of the lens, into which it is inserted tangentially about one millimetre in front of the equator of the lens. The middle fasciculus consists of a few fibres which are attached vertically to the capsule immediately behind the equator. The posterior cord is in close contact with the hyaloid, forms arches with their convexities forwards, and is inserted tangentially into the posterior capsule one millimetre behind the equator. Each of the cords is composed of separate fibres closely applied to each other. The canal of Petit is consequently bounded behind by the hyaloid membrane and in front is open to the posterior chamber by the spaces between the fibres of the anterior cord. Behind the ciliary process the fibres of the zonula decussate. The zonular fibres do not coalesce with the ciliary process, but extend over it for a considerable distance backwards, and they, with their epithelial investment, are continuous behind with the retina. The hyaloid membrane is quite independent of the fibres of the zonula. Much confusion has resulted from the non-recognition of this fact. At the ora serrata the retina becomes reduced to a single layer of columnar epithelium, which covers the choroidal epithelium as far as to the iris. Each of these columnar cells gives off a process which associates itself with that of the neighbouring cells. These collections of fibres gradually swell out to become zonular fibres and form the deeper layer of these fibres. At the ora serrata, in the eyes of the young and healthy, the retina slopes gradually into the ciliary epithelium. It consists here of supporting tissue only, or, more correctly speaking, of several rows of closely applied matted cells, the nuclei of which form two rows converging towards the ora. Here and there groups of cells form small villi which project from the retina. All of these cells send out processes like those above described, which run forward together and form the upper fibres of the zonula. The zonular fibres are thus nothing else than the elongated supporting fibres of the retina. In fact, the capsule of the lens is a continuation of the retina. It is doubtful whether the teeth—which, estimated at about forty in number, have given their name to the ora serrata—exist in the normal eyes of the child; macroscopically the ora forms a straight line, but there are many small villous processes at this part, and the name of ora serrata may be retained if no confusion is made between the above-named forty teeth well described by

HENLE and the 800 small toothlets formed by the villous processes. The microscopic teeth are gradually formed in association with the exercise of the power of accommodation as age advances. As the zonular fibres, which proceed from the retina, run chiefly to the anterior surface of the lens capsule, whilst those arising more anteriorly from the ciliary epithelium run chiefly to the posterior surface of the lens capsule, a decussation takes place which is seen at the internal angle of the ciliary body. The zonular fibres do not coalesce with the ciliary process, but are so interwoven with it that they are not easily detached. Seen on the flat surface of the process they form a kind of trellis-work of parallel fibres which stain easily with hæmatoxylin eosin.

The fibres of the ciliary muscle are divisible into three groups: the circular fibres at the inner angle of the ciliary process; the internal meridional fibres which take origin at the root of the iris and the angle of the ciliary body; and, lastly, the external meridional fibres which arise from the canal of Schlemm. Both of the groups of meridional fibres end in tendinous fibres, which are identical with the elastic lamellæ of the lamina fusca and suprachorioides. They penetrate the sheath of the optic nerve between the choroid and the retina. The anterior and posterior insertions of the external meridional fibres are relatively fixed. Their contraction causes an increase of pressure on the vitreous. The posterior attachment of the internal meridional fibres is relatively fixed, and the anterior relatively mobile. Their contraction draws the internal angle of the ciliary process backwards. The function of the external meridional fibres is chiefly to regulate the tension of the eye. The internal have the same action, but in addition keep the inner angle of the ciliary process in the right position and the lens at a proper optical distance.

After criticising the generally received theory of HELMHOLTZ to the effect that accommodation for near objects is effected by the contraction of the meridional fibres of the ciliary muscle, which relaxes the zonular fibres and thus permits the lens to become more convex, and those other theories which attribute accommodation to the action of the circular fibres of the ciliary muscle, to blood pressure exerted on the lens through the iris or the ciliary processes, to increased tension of the zonular fibres, and to change in the hydrostatic pressure in the anterior chamber, Dr. SCHOEN advances his own theory, which he thinks can best be understood from the following illustration. An elastic ball is to be grasped with both hands, the wrists being kept together. The ten fingers are then bent in so as to be applied to the ball along a line that, if the ball represented the globe, would correspond to the Arctic circle. If pressure be now made with the tips of the fingers the free part of the ball will bulge forwards. Now the finger-tips represent the ciliary processes and circular fibres of the ciliary muscle, the palms of the hands the meridional fibres of the ciliary muscle, and the two wrists the optic nerve. The anatomical relations, he contends, correspond completely to his theory for the anterior capsule. The zonular fibres and the retina form an investment to the vitreous humour and to the lens that are quite analogous to the elastic ball. The fibres of the ciliary muscle and choroid lie on the outside of the investment just as the palms of the hand are external to the elastic ball, and the ciliary processes form a similar groove, and exert the same kind of pressure

as the tips of the fingers in the above illustration. The depression caused by the ciliary process is always slight, never exceeding one millimetre.

IN accordance with the request of Her Majesty's Secretary for Scotland conveyed to them last May, the General Board of Commissioners in Lunacy for that country have furnished a special report respecting the Alleged Increasing Prevalence of Insanity in Scotland. This report has been published as a supplement to their last annual report. The Board at the outset say that no trustworthy information is obtainable in regard to assigned causes of insanity. They quote the following passage from their third report, published in 1861: "We should have been glad could we have presented a reliable statement of the causes of lunacy, but the information at our command on this subject is altogether untrustworthy." They go on to say that their experience subsequently to 1861 has not led them to modify in any degree the opinion then formed, that statistical tables founded upon the answers to the queries referred to (as to "supposed cause") would not only be quite valueless in throwing light upon the causes of insanity, but would be misleading. In addition to the natural disinclination to answer such queries, and to the impossibility of answering them where a patient's previous history is unknown, it may be observed that it is often impossible to say with certainty whether the supposed cause of the malady is really its cause or its effect; and that even when willingness to answer questions is present, when opportunities for observation are exceptionally good, and when the fullest knowledge is possessed of the patient's private history the true origin of the disease must often remain a mere matter of speculation. The Board go on to say that they do not know of any way in which it would be possible to obtain information as to the origin of the insanity of the patients on their register which would be of the smallest statistical or scientific value, and they have not therefore thought that any useful purpose could be served in dealing with the question from this point of view. The Board have from a very early period of their existence held and expressed the opinion that there is no statistical evidence that insanity is increasing. They state that they have dealt fully in their annual reports with many of the influences which they believe to have been sufficient to account for the increase of registered lunatics, and they allege that "none of them are such as involve the supposition that the increased number of registered lunatics is due to an increased liability to insanity in the community." In an appendix (E) the Board reprint the portion of their thirty-fourth annual report which deals with this question. Therein the following conclusions are drawn:—

1. That the increase of pauper lunacy is much beyond what would naturally result from the increase of population.
2. That it cannot be attributed to accumulation resulting from longer periods of residence of pauper lunatics in asylums.
3. That it is only in a very slight degree due to a lowering of the death-rate.
4. That there is no reason for believing it to be due to an increased tendency to insanity in the community.

5. That it is not due to any one cause.

In this same appendix they enumerate the following as among the causes of the increase of which they had spoken in former reports:—

1. The erection of new asylums for pauper lunatics, specially affecting localities in which no asylum accommodation for pauper lunatics previously existed.
2. The readier means of access to asylums due to increased facilities for travelling.
3. The gradual dying out among the public of feelings of dislike and suspicion towards asylums—a change which has resulted from an increasing recognition on the part of the community of the humane and enlightened methods of modern treatment and of the protection, comforts, medical treatment, and curative influences generally which modern asylums afford.
4. The greater readiness among the poorer classes to send relatives to asylums as pauper lunatics, which is due in part to the cause just mentioned, but also in part to a strengthened conviction of the difference which exists between the acceptance of parochial relief in cases of insanity and its acceptance under other conditions.
5. The growing unwillingness of the poorer classes to submit to all that is involved in keeping an insane relative at home (discomfort and expense, &c.).
6. The greater willingness of parochial authorities to recognise claims to parochial relief on the ground of insanity.
7. The stimulus, both to the readiness to seek relief and to the willingness to afford it, which has resulted from the giving of a State grant-in-aid towards the cost of maintenance of pauper lunatics.
8. The widening of medical and public opinion as to the degree of mental unsoundness which may be certified to be lunacy.

Three important memoranda are published as appendices to the special report. The first is by Sir ARTHUR MITCHELL, and deals with the Increase of the Number of Registered Pauper Lunatics, giving the results of the study of the statistics of the pauper lunacy in a locality specially selected as being best calculated to give an accurate view of what is really happening—viz., the Barony Parish, Glasgow.

ARTHUR MITCHELL'S conclusions are as follows: (1) that during the ten years 1883-92 there has certainly been no increased production of pauper lunatics; (2) that notwithstanding this the total number of lunatics chargeable to the parish has undergone a steady and considerable increase from year to year; and (3) that this has been due to an accumulation which results from the number of recoveries, deaths, and removals of unrecovered patients from the poor-roll being every year less than the production or crop of pauper lunatics.

The second paper, by Dr. SIBBALD, is a memorandum on the Increase in the Number of the Insane on the Register of the General Board of Lunacy for Scotland, with special reference to the allegation that it indicates an increased prevalence of insanity. This paper gives a historical summary of the conditions of the insane in Scotland prior to the passing of the Lunacy Act of 1857 and of the attitude of public opinion in regard to insanity during the first half of the present century. It then deals, among other points, with the influences upon the increase of numbers due

to the effects of the Act of 1857, the change in the character of asylums, the change of public opinion in regard to insanity, and the change of medical opinion in regard to the degree of mental unsoundness which justifies certification and the giving of the grant-in-aid. The conclusion which Dr. SIBBALD arrives at, from a study of the statistics, in the light of all the subjects referred to, is that they afford no evidence that mental unsoundness is to-day more prevalent in Scotland than it was. That no increase of insanity has taken place in that class of the community which is sufficiently wealthy to maintain its insane at its own cost is demonstrated by comparisons instituted by Mr. SPENCE, the secretary to the Commission, in the third paper, which is a memorandum on the Bearing of the Statistics relating to Registered Private Patients upon the Question as to whether Insanity is increasing.

The Board state that these three inquiries have been made in entire independence of each other, and have proceeded upon altogether different lines, and that all of them reach similar conclusions—conclusions which bear out their opinion, as expressed time after time, that the facts and figures, so far as they have been already collected and studied, afford no ground for a belief that insanity is to-day more prevalent in Scotland than it was thirty-six years ago, when the Board entered upon their functions.

Annotations.

"Ne quid nimis."

EPIDEMIC INFLUENZA : OFFICIAL MEMORANDUM.

WE publish elsewhere an official memorandum issued by Dr. Thorne Thorne, as medical officer of the Local Government Board, on certain preventive measures to be adopted against epidemic influenza. It is not difficult to see that the memorandum has been issued without much hope of preventing the recurrence of a disease which has already afflicted this country six times since the winter of 1889-90. When Mr. Shaw-Lefevre was asked in the House of Commons to issue a memorandum on the subject he cautiously replied that he would consider the matter; and when a second time Sir Walter Foster was questioned on the subject he frankly announced the views of the Board's medical department to the effect that not much good could be anticipated to result from the mere issue of a memorandum. And in the issue now made in deference to requests in the House of Commons it is easy to see that the medical officer has no great hope in any general measures of prevention. He refers to the facts that influenza is often infectious before it is recognised, that it is often never diagnosed at all, and that its incubation period is of the shortest. These conditions alone make the disease a most difficult one to grapple with from the preventive point of view; and when it is further remembered, as Sir George Buchanan put it in 1891, that owing to the brief incubation period one case of influenza can "give rise to some thousand attacks in the time that small-pox or typhus had taken to produce ten" it will be evident that the mischief is generally produced before the prevention can be applied. Then, again, the number of mild, but still infective, cases in which any sort of preventive control becomes impracticable is such as to make the question one of exceptional difficulty. If, however, aged and infirm people take note of the precautions suggested some fatality at least will be saved. And if in acute cases, where some control can be exercised,

isolation of the sick and disinfection of sputa be insisted on, further diffusion of the disease may to some extent be arrested.

THE PERILS OF FOOTBALL.

AN inquest was held at Hexham on Friday, March 8th, on the body of a player, who died on March 5th from injuries received in a football match, played under Rugby Union rules, on the previous Saturday. On a verdict being returned in accordance with the medical evidence, which showed that the unfortunate man had died from the effects of a collision between his head and the hip of an opponent whom he was attempting to "collar," the jury added a recommendation that a revision of the Rugby Union rules to make the game less dangerous was necessary. With this sentiment we are in accord, but we should like to see the suggested revision of the rules of either code; we should like to read some serious proposals for lessening the perils of the game which had emanated from players thoroughly familiar with all the details of both codes. If the recommendation of the Hexham jury brings such a revision into the sphere of the practical politics of the football world it will have done a great thing, but we fear that to this we cannot look forward. It has been our practice to issue now and again a summary of the severer accidents that have come under our knowledge as having occurred in the football field, and as the result of much practical experience we have been unable to see in what direction the rules of either code could be revised so as to lessen the dangers without spoiling the game. And whoever spoils the game places himself in the responsible position of depriving an enormous number of his fellow-citizens of the incalculable benefits to be obtained from a form of exercise which appeals by its splendid athletic possibilities as much as by the moderation of its demands on their time and purse to the whole of the younger generation. Though we do not think that the recommendation of the Hexham jury will have practical effect in leading to a revision of the rules—because we do not see in what way such revision is to be made—we think that it cannot but have a distinct value in one direction. It will cause the public to see that it is possible to raise a voice against the obvious perils of football without being necessarily a namby-pamby sentimentalist or desirous to keep the youth of the country permanently swaddled in cotton-wool. Great things are not to be expected from revision of the rules; for though we have heard the opinion expressed freely and frequently that such revision should be at once effected, we have never been able to find any practical player who could suggest any changes, either by altering or rescinding existing clauses, that would obviate any of the perils of the game. But great things may be expected if the mass of players can be compelled by a severer penal code to preserve a better spirit. The powers of the referees must be further extended, and the penalties for foul play and insubordinate behaviour made prohibitive. A verdict of manslaughter brought in against the whole of both sides is but one step in advance of the verdict, with its rider, that we chronicle above. When this occurs the authorities in the football world will recognise that an unchecked evil has grown up amongst them. Why do they not see it now? We appeal to all right-minded players. There is nothing effeminate in putting down brutality with a strong hand. Why not begin?

ELECTRIC LIGHT MAINS AND THEIR DANGERS.

AN accident occurred at Bristol on Feb. 25th which resulted in the death of a workman and was probably due to a momentary inadvertence on his part. It appears that it was the duty

of the man in question to remove the dust from a high tension fuse board, and whilst doing this with the right hand covered by an indiarubber glove the left hand (bare) seems to have touched a fuse terminal, and thus his body made contact to earth with the 2000-volt main (the second condition of contact referred to at p. 281 of *THE LANCET* of Feb. 2nd). It appears from the evidence of the corporation engineer that there were no printed regulations for the guidance of workmen employed on this particular duty, but it was the rule that when engaged on high tension work one hand only should be used, and that hand covered by an indiarubber glove. The story of this accident is no doubt the old story of carelessness; but there may be room for doubt as to whether this carelessness was entirely on the part of the workman who suffered. Assuming that it was necessary to clean this apparatus whilst the electric current was passing over it, were the insulation precautions adequate? As a matter of fact, ought this man to have been at work on this "live" high tension apparatus without being duly insulated from the earth? Might he not have been provided with an indiarubber mat and boots as well as with gloves for both hands, with at the same time an imperative caution staring him in the face never to relax the paramount rule of working only with one hand?

THE RAM, THE BULL, THE HEAVENLY TWINS.

A CORRESPONDENT, writing from that grave haunt of learning, the *Athenæum*, makes a suggestion which, although admirable in itself, savours rather of the philosophy of Laputa than of present-day science. Since, he says, twin calves are sterile, if the same condition obtains among human beings a wide field is open to twins in the nursing of phthisical patients, for it is a well-known fact that patients recovering from illness are more apt to fall in love than at any other period of their life, and thus the baneful disease of phthisis might not be handed down to posterity more than is absolutely necessary. Now, if we allow the premisses, the conclusion is excellent; but, unfortunately, the theory does not fit in with the facts. Twins of the bovine species undoubtedly often are sterile, some of them are generally more or less hermaphrodite. But it is far from being the rule, as numerous instances are on record where twins of both sexes have proved fertile. Amongst sheep, generally uniparous animals, it is not uncommon for an ewe to have two, three, four, or even five lambs at a birth, but no complaints have been made as to their being sexually defective, and in the human race twin children, even when boy and girl, are no more impotent or sterile than other children. We are afraid, therefore, that our correspondent's well-meant suggestion for checking the hereditary transmission of phthisis is impracticable, but it may comfort him to know that statistics show the percentage of phthisical cases who have a family history of the disease is only 33 to 36 per cent., so that, roughly speaking, even under his régime, there would still be left some 65 per cent. of cases.

DIPHTHERIA IN LONDON.

FOR the fourth week in succession diphtheria in London showed a rise in the matter of fatality, the deaths having been in the past five weeks 34, 27, 29, 31, but last week 34. Thus the disease would appear to have reached a stage at which it is difficult to improve its fatal aspect. Nevertheless, the decennial average for the particular week was exceeded by 9, though, on the other hand, all the deaths were in persons aged under twenty years, pointing to school influence in the cases. As many as 26 cases were in young children under five years of age. Of the total, 4 belonged to St. Pancras and 4 to Greenwich, 3 each being credited to Hackney, Bethnal Green, Battersea, and Camberwell sanitary districts. There were in the hospitals of the Metropolitan

Asylums Board on Saturday last 454 cases of diphtheria, there having been a continuous fall since the week ending Jan. 26th, when the number stood at 528, but the admissions do not appear to be any accurate criterion of the actual amount of the disease in London. The admissions last week numbered only 55. In Greater London there were 11 deaths registered from diphtheria, of which 4 belonged to West Ham and 2 to Edmonton districts.

HOSPITAL SATURDAY AND SUNDAY IN MARYLAND.

THE Hospital Saturday and Sunday Association of Baltimore was instituted in 1882 by the Hospital Relief Association of Maryland, U.S.A., and has recently issued its thirteenth annual report. In 1894 the collections were made on consecutive days—viz., on Nov. 24th and 25th, the amounts contributed being \$590 on the Saturday and \$1280 on the Sunday; the total was therefore \$1880, or about £384, in which fifteen hospitals and homes were entitled to share. The Hospital Relief Association, although closely connected with the Saturday and Sunday Association, publishes a separate annual report, which shows that its philanthropic operations are mainly carried on by lady workers, and that its financial position is very satisfactory.

MYSTERIOUS DISAPPEARANCES.

THE heading "Mysterious Disappearance" is not at all an unusual one in the pages of our contemporaries, morning and evening. As a rule the heading is the introduction to an account of the sudden and unaccountable disappearance of some man or woman, occasionally on the eve of some important event, but more frequently under circumstances which do not present even that excuse for an explanation. Doubtless it occasionally happens that some sufficiently strong reason for the disappearance in the shape of financial or other embarrassments is discovered in the course of days or weeks; but even after all allowance is made for such presumably intentional disappearances a certain number remain unexplained and inexplicable. We have often wondered what the sequel to such an occurrence is, but if ever there is a sequel it must occur when the memory of the mysterious disappearance has faded from the minds of all except an interested few; and even if the reappearance is occasionally chronicled it has nothing like the dramatic significance which the disappearance had, and but rarely evokes comment or excites interest. Yet to the psychological student these events present a most interesting problem, and a recent article by Dr. Osborne in the *Medical-Legal Journal* on People who Drop out of Sight appears to afford food for thought, not only to the student, but even to the proverbial "man in the street." The first case mentioned is that of a man, thrifty and industrious, prosperous in his business, and exemplary in his family relations, who left his house one Sunday afternoon to have a short walk, being reminded by his wife as he went out not to be late for dinner, which was to be ready in a few minutes. He did not return, no trace of him could be found, and no reason for his disappearance was discovered when his affairs came to be wound up, as they had to be in the course of time. Two years later, in a shop in one of the southern States of America, a man who had been known as an industrious, although taciturn, workman suddenly seemed to wake up and asked where he was and how he had got there. Gradually things came back to him; he remembered leaving his house in the north on a Sunday afternoon two years before, but everything that happened subsequently was as if it had not been. Nothing of his wanderings could be discovered further than that some months before he had appeared in the town in which he came to himself, and had asked for and obtained work, which he had performed diligently and

efficiently. He was restored to his family, and at the time the article was written had resumed his former life. Another and even more striking case is related—that of a lawyer, a well-known public man and politician, of more than usual ability and in a prominent social and professional position. One day, while in the midst of some intricate and important legal work, he stepped outside for a few minutes. He also disappeared. The most vigorous and thorough search failed to discover him, dead or alive. Streams and reservoirs were dragged, woods were searched, and every means at the disposal of wealth and influence were used to discover his whereabouts. He was known to be abstemious in his habits and happy in his home, and a searching examination of his business affairs failed to reveal the slightest irregularity in them. Several months passed, when at length word came through Government channels that the missing man was in Australia and was applying for means of establishing his identity and procuring his transportation home. He was successful in satisfying his friends of his identity, money was transmitted to pay for his passage, and in due time he arrived. After a short period of rest he resumed his professional work and has since continued to be just as he was before his sudden and quite unaccountable disappearance. It is an interesting question, How are such cases to be accounted for? The suddenness of the disappearance, the absence of motive, and the utter inability of the patients to give even the slightest account of their experiences during the time which elapses between their disappearance and their coming to themselves, all give a certain weird character to these aberrations. Are they of the nature of post-epileptic phenomena? Are they lapses into an *alter ego*, and if another such lapse occurred would the patient take up the thread of this second existence where he had dropped it to resume his, what we may call, ordinary identity? These are interesting questions. Unfortunately they are unanswerable. All that we can say is that these disappearances partake of the character of post-epileptic phenomena, and that in some patients who have suffered from lapses similar to, if not so severe as, those just described a more or less definite history of true fits of epilepsy has been obtainable. And another thing is also significant—viz., the very close resemblance that these attacks bear in their character, if not in their duration or severity, to somnambulism, while the relation which this bears to epilepsy, if not very definite, is certainly close. Yet whatever theory is put forward to explain such phenomena as those just referred to, they remain striking and mysterious, interesting in their psychological aspect, but in their concrete form full of practical and medico-legal difficulties.

SOME AUSTRALIAN DANGERS TO LIFE.

SYDNEY SMITH once said that Nature, having made all sorts of useful animals and birds for other parts of the world, seemed determined, when supplying organic life for Australasia, to give free play to her fancy. "Accordingly she made cherries with the stones outside, a monstrous animal as tall as a grenadier, with a tail like a bed-post, hopping along at the rate of three hops to a mile, with several young ones looking out of its false uterus, and a kind of mole with webbed feet and the bill of a duck, which agitated Sir Joseph Banks and rendered him miserable from his utter inability to decide whether it was a bird or a beast." We are led to quote these somewhat frivolous remarks by having just received a very interesting anniversary address, delivered before the Royal Society of New South Wales by Dr. Anderson Stuart, in his presidential capacity, on May 2nd, 1894. The animal which agitated Sir Joseph Banks was the *Ornithorhynchus paradoxus*, a curious survival of a very primitive type of animal. For a long time it was considered to be quite harmless and destitute of any weapon of offence,

although the hind legs of the males were armed with a powerful spur, apparently connected with a gland. Then the opinion was advanced that this might be a weapon allied to the poison armoury of snakes, scorpions, and bees, all of which possess a sort of hypodermic poison syringe. Though one set of observers asserted that this was the case another set denied it, and so Dr. Stuart determined, if possible, to solve this question. He received two independent accounts, which coincided perfectly, and from them he concludes that at certain seasons, at all events, the secretion is virulently poisonous. The mode of attack is not by scratching, but by lateral inward movements of the hind legs. Two cases are reported in dogs. One dog was "stung" three times, the symptoms much resembling those from bee or hornet poison. The dog was evidently in great pain and very drowsy, but there were no tremors, convulsions, or staggering. It is worthy of note that a certain immunity seems obtainable, for the dog suffered less on the second occasion and still less on the third. Two cases of men being wounded are reported, in both of which the animals were irritated, one by being shot and handled, the other by being handled only; the symptoms were the same as in the dog. No deaths are reported in human beings, but four in dogs. Another poisonous animal is the red-backed spider—*Lathrodectus*—though the Sydney variety does not seem so virulent as *Lathrodectus decempunctatus*, from which Professor Kobert obtained a poison so powerful that $\frac{1}{2}$ gr. would kill a man twelve stones in weight. Many instances of fatal results from the bite of these spiders are recorded. Another pest very fatal to dogs is a bush tick. In this case also one attack confers immunity from a second, and in districts where they abound dogs are frequently immunised by letting the tick remain until the first symptoms appear and then removing it. Upon complete recovery this is repeated. Other portions of Dr. Stuart's highly interesting address dealt with vaccination for anthrax, most successful in the case of sheep, disposal of sewage, and sanitary legislation.

A PERAMBULATORY KITCHEN FOR THE POOR.

IN the current number of the *Nineteenth Century* Miss Sellars makes an appeal for the establishment in London of people's kitchens as in Vienna. Mr. Frederick Greenwood, commenting on this in the *Pall Mall Gazette*, makes the very sensible suggestion that the stationary kitchen should be supplemented by a "flying one," to use a military term. "Suppose," says Mr. Greenwood, "a kitchen built of fair amplitude, and with every appointment of economy and cleanliness visible at a glance. From this kitchen (or from a dozen such) a smart van starts off at the midday hours to go its rounds. The van is broad and deep, like those employed for moving furniture from one house to another. Glaringly clean, it is fitted up with trays and other receptacles heated by mineral oil or portable gas. The various receptacles contain three or four kinds of food appropriate to the dinner hour; which kinds are not the same every day, but are always wholesome, always savoury, and such as are well liked of those for whom they are provided. Milk is distributed from door to door in cans, as beer used to be: why not close-covered cans of hot, strong, newly-made soup, or of 'Irish stew'? Small puddings—meat puddings, plum-puddings; fish fresh drawn from the bubbling pan; roast potatoes; potatoes fried; portions of well-cooked beef; portions of mutton stewed in rice: such viands as these might be carried round, hot and good, with dishes of cold meat and salad in the summer time." We most cordially endorse this suggestion. The mere fact of giving the poor an opportunity of choosing from a variety of dishes would be an inestimable boon. Anyone who has been in and out of the homes of the poor will remember that they

have but one way of cooking things—i.e., they are “done” in a frying-pan, not properly fried—that is, boiled in fat—but burned and made greasy. Any kind of stew or tasty compound of scraps of meat and vegetables with rice is unknown. On Sundays they have a bit of baked meat with potatoes under it. Soup is never made. The experiment of taking food to workers who have neither the time nor the place to prepare it has been tried on a small scale with great success by the Sisters of the Church Extension Association with their food truck at the Docks. The expense of starting one of these kitchens would not be very great and it would be well worth the while of the various charitable societies to combine and make the experiment.

REGISTERED DENTISTS.

THE Dentists' Register for 1895 shows that there are 4874 registered dentists in the United Kingdom. Of these the great majority, 3479, practise with no special qualification, but on the strength of their own declaration that they were engaged in the practice of dentistry before the passing of the Act. A few of these have taken qualifications. The new registrations during last year of dental practitioners have been 84. Of those on the Register 1363 hold a licence in dental surgery; they are distributed among the following colleges as follows: the Royal College of Surgeons of England, 663; the Royal College of Surgeons of Edinburgh, 133; the Faculty of Physicians and Surgeons of Glasgow, 113; and the Royal College of Surgeons in Ireland, 454. There are eleven doctors of dental medicine of the University of Harvard on the Register, and sixteen doctors of dental surgery of the University of Michigan. Our readers are aware that the registration of the degrees of these universities has been for the present discontinued.

THE LATE SIR WILLIAM SAVORY.

WE have been favoured by Mr. Oliver Pemberton, F.R.C.S. Eng., with an inspection of a letter written to him by the late Sir William Savory on Feb. 25th with reference to Mr. Hulke's death. It is interesting to record Sir William Savory's words, written as they were little more than a week before his own death: “Hulke was the most accomplished man in the profession, and the loss of him the greatest that could have befallen it; and this not from his great learning, but because of his integrity and honour.” After referring to Mr. Hulke's somewhat reserved nature and to the long and intimate friendship which existed between Mr. Hulke, Mr. Oliver Pemberton, and himself, he closes his letter with the words: “Personally I cannot measure the loss.” The friendship between Sir William Savory and Mr. Pemberton was accentuated by the fact that in “college politics” certainly, and on many other subjects probably, they held very divergent views.

Previously to the interment of the remains of the late Sir William Savory at Highgate Cemetery on Thursday, March 7th, a memorial service was held at St. George's Church, Hanover-square, the Rev. David Anderson officiating. The chief mourners were Sir Borradaile Savory, son of the deceased baronet, and his wife, Lady Savory; Dr. Savory, brother of the deceased; Mr. Henry Morris; Mr. Green-side; and the Rev. Dr. Cosmo Gordon. Among those who attended the service were Sir James Paget, Bart., F.R.S.; Sir William Broadbent, Bart.; Sir William Flower, F.R.S.; Sir William MacCormac; Dr. Habershon; Lieutenant-Colonel Moon; Mr. Howard Marsh; Sir Trevor Lawrence, Bart., treasurer of St. Bartholomew's Hospital; Sir Dyce Duckworth and Lady Duckworth; Dr. Constantine Holman; Dr. Thorne Thorne, C.B., F.R.S.; Mr. Thomas Bryant; Professor Stewart; Mr. Thomas Smith; Canon Elwyn, Master of the Charterhouse; Sir Henry Edwards, Bart.; Mr. Reginald

Harrison; Mr. Alfred Willett; Canon Phillips; Colonel Black; Dr. Shore, Warden of St. Bartholomew's Hospital; Mr. Dickins; and Mrs. Walter Spencer, on behalf of the Royal British Nurses' Association. The floral tributes were very numerous, amongst them being one from the students of St. Bartholomew's Hospital with the arms of the institution wrought in primulas and violets. The floral offering of the matron and sisters consisted of lilies of the valley tied with black ribbons, representing the well-known magpie colours of the hospital. A wreath was also sent by Princess Christian, President of the Royal British Nurses' Association, in which the deceased surgeon took a very great interest. The Rev. Dr. Cosmo Gordon officiated at the graveside service.

THE FOOD AND DRUGS ACT IN THE CITY OF LONDON.

IN his capacity as public analyst for the City of London Dr. Sedgwick Saunders reports that 161 analyses were made in 1894 with the result that in no case was it deemed necessary to institute any prosecution, although some of the articles examined were perilously near adulteration. These included several milks which were “below the standard of every analyst in the kingdom excepting those who direct the chemical work at Somerset House, who still refuse to adopt the standard fixed by the Society of Public Analysts.” Whilst the number of samples taken for analysis during the year in England and Wales was equal to one for every 779 of the population, in the City of London one sample was examined for every 347 persons, so that the conclusion that “the articles supplied by retail traders throughout the City are fairly genuine on the whole” is based upon a higher proportion of articles analysed per head of the population than in most other districts. As in previous reports, Dr. Saunders calls attention again to the necessity of improved administration of the Act, as illustrated in the question of standards (for milk principally), the mode of collecting samples, the inadequacy of fines, and the leniency of magistrates in dealing with proved offences. These points each and all were discussed in an article in THE LANCET of March 2nd, 1895, and we are glad to find that the analyst for the City of London is using his influence towards effecting much-needed reforms on the lines we have again and again indicated.

THE DIFFUSION OF SMALL-POX.

THE record of small-pox occurrences in London was last week identical with that of the preceding week, the fresh cases having been 8 in number. No death from the disease was registered, and all the new cases were removed to hospital, the number of patients remaining under treatment last Saturday being 54, a decrease of 14 on the total of the previous week. In the six weeks ended last Saturday there have been notified in London 83 cases of small-pox, and 8 deaths have resulted, nearly 10 per cent. of mortality. In the four weeks ended with the 23rd ult., of a total of 67 notified attacks, no less than 57 belonged to the parish of St. Mary-lebone. It is, at any rate, satisfactory to see that a recrudescence that augured so badly for that parish has been controlled in such a manner as the recent data would appear to indicate. The only news of any account coming from the home counties in respect of last week is concerning a few cases of small-pox at Bedford, but not of much moment, we trust, for that borough. In the Midlands there were again but very few cases at Birmingham, this continued record of slight invasion of that city as compared with previous months seeming to point to permanent abatement of the disease. Northward, however, the borough of Derby registered another death from small-pox last week, and several attacks are chronicled. The disease

seems to have been smouldering there for some little time past, but the sanitary department is actively engaged in dealing with the present reappearance of the infection. Reassuring news comes from Liverpool and its suburbs, the small-pox of last week having been insignificant in amount in the city and surrounding districts. The last week of February witnessed 2 deaths from small-pox in Edinburgh, where 4 deaths from the disease were registered in the month, Glasgow having had 2 deaths registered in the month. In Dublin in the week ended March 2nd, the admissions of small-pox cases to hospital numbered 31, a decrease of 6 on the number of the preceding week, and of 25 on the week ended Feb. 16th. The discharges again outnumbered the admissions, having been 52, and the deaths were 4, all in unvaccinated persons, 2 at ages between five and twenty years, and 2 at ages from twenty to forty. At the close of the week the acute cases under treatment were 110 in number, as compared with 135 on the previous Saturday, and with the convalescent patients at Kilmainham the total still under isolation was 235. During the nine weeks of the present year the admissions were 537 and the registered deaths 63, a percentage of mortality of nearly 12 on the admitted cases; but everything points to a steady decline in the epidemic.

THE STANDARD AGE FOR CHILD LABOUR.

It is significant of an increasing perception of the value of education that many persons in the present day are dissatisfied with the standard age limit which regulates the labour of children in this country. The allotted minimum of eleven years is represented in France and Germany by that of fourteen, and in other countries of twelve years. A system which allows of earlier occupation has about it a certain aspect of commercial convenience. We are not, however, disposed to defend it on this ground. We cannot but think that any such apparent advantage is likely to be rather dearly purchased at the cost of other present and solid advantages and likewise of ultimate efficiency. The work a boy will do in the first year, or indeed in the first two or three years, after leaving an elementary school must be of comparatively small consequence either to himself or his employers. The same period spent in learning would very materially add to his intelligence when at its close he entered the working ranks. It might, and in our opinion should, be spent partly, if not entirely, in acquiring some technical knowledge with a view to later and more intimate acquaintance with the trade to be pursued through life. By such an arrangement we might expect to increase the most justly valued class of workmen in this or any other country—namely, those thoroughly versed in a professed calling—and to reduce the numbers of the comparatively aimless and inefficient "Jacks" who are masters of none.

ISOLATION ACCOMMODATION IN CHESHIRE.

UNDER the provisions of the Isolation Hospitals Act, 1893, Mr. Francis Vacher has recently made for the Cheshire County Council a full report upon the isolation provision at the present time possessed by the several sanitary authorities throughout the administrative county. Although Mr. Vacher's report has reference, in the first instance, to those districts to which the Isolation Hospitals Act more particularly applies, he has embraced in it a description of the accommodation possessed by the county boroughs in Cheshire, as also by the municipal boroughs, whether or not they possessed at the last census 10,000 persons. Mr. Vacher gives a short history of each hospital, an account of the building, the number of diseases and patients for which provision is made, and much other useful information. After making certain deductions in regard to the population of the administrative county, Mr. Vacher concludes that on

a basis of one bed per 1000 of the population the urban and rural districts of the county should provide 533 beds. At present there are but 238, and, many of them being in temporary buildings, Mr. Vacher reckons that the number of beds actually needed is some 370. Having arrived at this estimate, he thence proceeds to discuss in what portion of the county additional accommodation is required and in what positions hospitals can conveniently be erected. For the purpose of the report the county is divided into an eastern, central, and western portion, and suggestions are made in each case for the provision of certain joint hospital boards.

FINES UNDER THE MARGARINE ACT.

AN important concession in regard to the working of the Margarine Act is being sought by the vestry of Shoreditch. It appears, according to a letter in a morning contemporary from Mr. Harris, the medical officer of health for Islington, that hitherto the invariable practice of magistrates has been to refuse to hand over the fines inflicted under the Margarine Act to the sanitary authorities, upon whom all the expenses incidental to the enforcement of the Act devolve. We quite agree with Mr. Harris that the Margarine Act would receive a healthy stimulus if the resulting fines could be handed over to the prosecuting authorities, as is the case with the Food and Drugs Act. Both Acts have practically one common object in view—viz., the prevention of fraud and adulteration—and their administration should surely, therefore, be placed upon the same basis. We trust the Home Secretary will use the powers he possesses to sanction the request which, as it seems to us, the authorities are reasonably urging.

THE EAST-END MOTHERS' HOME.

WE have received the report of the East-end Mothers' Home for the year ending Dec. 31st, 1894, with an intimation that the annual meeting of those interested in it will be held on the 18th inst. It appears that the in-patients during the year were 218, and the patients attended at their own homes were 284, in both cases marking an increase on the numbers in the previous year. We see that there were two deaths among the out-patients, and one among the in-patients. In order, however, for statistics on this matter to have scientific value it would be necessary to know at what period patients are discharged after confinement, and also in what condition—that is to say, were any patients discharged who could not be fairly classed as quite well? And, still further, were any patients who were seriously ill either sent to their homes or sent to some general hospital, as we are informed has been done on some occasions? and if so, did any such cases die, or only recover after a longer or shorter illness of more or less gravity? Two other points occur to us after reading the report and balance-sheet. One is that apparently the women attended at their own homes are charged a fee of 3s. 6d. each for such attendance. This certainly appears to us undesirable in many ways on the part of a charitable institution appealing to the public for support, and receiving, as we see it does, grants from the Hospital Sunday and Saturday Funds. Moreover, it appears contrary to the design of the home itself, as given on p. 3 of the report, which is "to maintain in the east of London a home for the treatment of poor married women during childbirth, free of any charge to the patients, also for training midwives and nurses for attendance on the poor at their own homes." The other point is that apparently the whole of the regular work of the institution, both as regards in-patients, out-patients, and instruction given to the midwives, is performed by one medical man. If we remember rightly there were formerly two visiting medical officers; and for many

reasons it appears desirable that an institution such as the East-end Mothers' Home should have an active staff of not less than two medical men. With only one medical officer the efficiency of the institution is obviously at the mercy of chance. Unavoidable absence and illness occur to every man. There could be no difficulty in obtaining the services of at least one other medical officer, as there are plenty of well-qualified men in the district, some one of whom would no doubt be willing to serve.

PREVENTIVE LAW.

THE Leyton Local Board has been condemned by Mr. Justice Cave in the Queen's Bench Division to pay Mr. Henry Eustace, a carpenter, damages to the amount of £100. It appeared that at the rear of the plaintiff's house there was a pit into which the local authority shot a quantity of refuse. There had been cases of illness both in the plaintiff's family and in houses close at hand, but there were also infectious fevers throughout the neighbourhood, and there was no evidence whatsoever to prove that this particular accumulation of rubbish had been the cause of disease. The whole of the medical evidence went to show that the nuisance in question had not caused any outbreak of illness. Nevertheless the jury, without even leaving the box, found for the plaintiff with £100 damages. This verdict, we take it, means that dust and refuse must not be shot near dwelling houses. Undoubtedly there can be no objection to such a regulation. It is something to know that what is likely to cause disease must be removed, and that, if it is not removed, damages can be obtained, even though no damage has been done. We hear a good deal about preventive medicine, but this is truly preventive law. It is not every day that we find juries, in so emphatic and unhesitating a manner, establishing this principle of prevention. The refuse, it was pretty evident, had done no harm; still, it might have done harm or might do harm in the future if allowed to remain there, therefore the verdict was for the plaintiff, and the local board was punished for its neglect by having to pay a handsome sum in damages.

THE INFLUENZA EPIDEMIC.

As influenza does not appear in the list of notifiable diseases it is not possible to obtain any accurate notion of the extent of the present visitation; but there seems little doubt that the disease is being widely diffused throughout the country. The mortality from respiratory diseases remains exceptionally high, for although the Registrar-General's returns showed a slight diminution in the total deaths from this cause in London during last week—viz., 1366, as compared with the preceding week's return, 1448—yet it is noted that the corrected average was exceeded by 842. It is remarkable, on the other hand, that the deaths "attributed directly to influenza" should have risen from 296 in the week ending March 2nd to 473 in the following week, and as in all probability these cases due to influenza were mostly diseases of the respiratory system their subtraction from last week's return would reduce the mortality of the latter to very nearly the corrected average. As stated last week, we believe there is no doubt that the epidemic, so far as London is concerned, has subsided very materially in extent; but if anything approaching these high death-rates continues to be maintained it would prove that it is increasing in intensity. It must, however, be remembered that arguments on this score based on death returns alone are open to fallacy, since they by no means coincide with the epidemic wave. We shall be surprised if the returns of the present week do not show a very marked diminution in the mortality from influenza. It may be observed that the estimated annual death-rate in the thirty-three great towns of England and Wales amounted

last week to 35.0 per 1000 of their aggregate population, a rate exceeded by Brighton (40.1), Halifax (42.8), Liverpool (45.2), London (41.2), Nottingham (37.7), Plymouth (48.0), and Preston (35.2). These rates, it is needless to say, are considerably above the mean rate at this period, the variation being notably so in some of these towns.

THE CARE OF AND ATTENDANCE ON THE INSANE.

WE learn that the Medico-Psychological Association of Great Britain and Ireland is about to hold an examination with a view to granting a certificate of proficiency in nursing and attending on the insane. The next examination will be held on Monday, May 6th, 1895. Schedules to be filled up by the candidates can be obtained from the registrar (Dr. Spence, Burntwood Asylum, near Lichfield), and the schedules, duly filled up and signed, must be returned to him at least four weeks before the date fixed for the examination. Monday, April 8th, will be the last day upon which, under the rules, candidates can enter their names for examination.

THE UNIVERSITY OF CAMBRIDGE AND THE EXTENSION OF SCIENCE TEACHING.

WITH reference to our remarks last week on the extension of science teaching, Dr. Joseph Griffiths, the hon. secretary of the Cambridge Summer School of Medicine for Qualified Practitioners, has supplied us with the following programme in advance. During the week beginning Monday, July 1st, and ending Saturday, July 6th, 1895, there will be clinical demonstrations at Addenbrooke's Hospital from 10 A.M. to 11.15 A.M. by members of the honorary medical and surgical staff; demonstrations with experiments illustrating subjects of clinical interest on alternate days from 11.30 A.M. to 1 P.M. in the Physiological Laboratory by Professor Foster and in the Pathological Laboratory by Professor Roy; and demonstrations in the afternoons daily in the Medical Schools by Professor Sir George M. Humphry, F.R.S., Dr. Annington, Dr. Joseph Griffiths, and Mr. E. H. Douty, M.B.; in the Anatomical Department by Professor Macalister, F.R.S.; in the Pharmacological Laboratory, Downing College, by Professor Bradbury. There will also be lectures on special subjects in the evenings, at 8.30 P.M., by Professor T. Clifford Allbutt, F.R.S., Dr. Norman Moore, and others. On the Monday night, at nine o'clock, a conversazione will be held in the Physiological Laboratory, New Museums, when a short address will be given by Professor Sir George M. Humphry. For those accommodated in college, breakfast, lunch, and dinner will be provided in hall; and for those not accommodated in college, dinner (and it may be lunch) will be provided in the hall of one of the colleges. On one afternoon a garden-party will be given in the Fellows' Garden at King's College by Sir George and Lady Humphry. On other afternoons parties of visitors will be conducted round certain of the colleges. It should be noted that this programme is necessarily subject to revision in detail.

THE PEABODY TRUST.

THE trustees of the Peabody Donation Fund have recently issued their annual report for the year 1894, which contains the usual record of useful work and judicious management. The fund, which was founded by Mr. Peabody in 1862, and was afterwards increased by him from time to time to the magnificent total of half a million sterling, has, under the careful stewardship of the trustees, been more than doubled, and was valued at the end of last year at considerably more than a million pounds. The Peabody Buildings included at the end of the year no fewer than 11,261 rooms, besides bathrooms, laundries, and lavatories, in which resided 0

Dec. 31st last 19,918 persons. The average rent of each dwelling was slightly less than 5s., and of each room rather more than 2s., the rent in all cases including the free use of water, bathrooms, laundries, and sculleries. The births among the resident population of these buildings in 1894 were equal to 36.3 per 1000, which was 6.3 per 1000 above the aggregate rate in London. The rate of mortality was only 15.7 per 1000, and 2.0 below the average rate in the whole of London. This death-rate includes 49 deaths of residents of these buildings that occurred in various hospitals, but it does not appear to include any correction for deaths of residents who drift into the workhouses and workhouse infirmaries, and this undoubtedly explains, at any rate in part, this remarkably low death-rate in a distinctly working-class population. The trustees of this fund have not made much addition to their buildings for several years, but have been employing their surplus revenue in repaying the sum of £390,000 borrowed from the Public Works Loan Commissioners, which has thus been reduced to £111,000. It is stated in this report, moreover, that since the beginning of this year two new blocks of buildings in Stamford-street, containing 110 rooms, have been occupied, which must have raised the resident population above 20,000 persons. The housing of this large population in improved and sanitary dwellings is a grand result from the operation of the Peabody Fund, and it is inevitable that the scope of its benefits will be very considerably increased in the not distant future.

THE BUCKINGHAMSHIRE SANITARY CONFERENCE.

THE report of the proceedings of this Conference, which was held at Aylesbury on Oct. 31st of last year, has recently been issued in pamphlet form, together with an introduction by Miss Florence Nightingale. Our readers will remember that in THE LANCET of Nov. 10th we gave a short account of the eminently successful Conference, and we are glad now to have an opportunity of drawing attention to the report. The Conference was held under the presidency of Mr. Frederick Verney, chairman of the sanitary committee of the Bucks County Council, and we believe we are right in saying that at the time of the Conference the relations between the sanitary committee and the council as a whole were such that many members of the council were desirous of terminating the existence of the committee. Fortunately, however, the very influential conference which Mr. Verney was instrumental in calling together, and the publicity which was given to its proceedings, succeeded in bringing home to the council the advantages from an administrative standpoint of a sanitary committee, and we are now able to chronicle that the life of the committee has been prolonged and received fresh vigour. Miss Florence Nightingale, in her introduction, points out that "money would be better spent in maintaining health in infancy and childhood rather than in building hospitals to alleviate and cure disease," and in saying this she places her finger upon a great blot in preventive medicine—our heavy infantile mortality. We can but feel that the Bucks Sanitary Conference has done well to publish its proceedings in their present form, as the circulation of the pamphlet cannot fail to assist in bringing about that popular education in sanitary matters to which one of the speakers more especially drew attention. We again congratulate Mr. Verney upon the success of his enterprise, and trust that all newly elected district councillors in Buckinghamshire will make themselves familiar with the contents of the report. There are few counties in our knowledge where there are better opportunities for sanitary reform than Buckinghamshire, and more especially is this the case with regard to isolation accommodation and the housing of the working-classes.

IN consequence of the recent indisposition of Sir John Erichsen (from which he is, we are glad to say, rapidly recovering) the complimentary dinner to him and his distinguished colleagues Sir J. Russell Reynolds and Sir John Williams, which we announced would take place on Wednesday, March 13th, has been postponed to Wednesday, March 27th.

AT the Council held on March 13th, the resignation of Alderman Vaughan Morgan as treasurer of Christ's Hospital was accepted, but he will continue to act until a successor is appointed. Alderman Vaughan Morgan remains treasurer under the old governing body of the endowments excepted from the scheme.

DR. LIDDELL, the former Dean of Christ Church, Oxford, presided at a meeting held in the Sheldonian Theatre, Oxford, on Friday, March 8th, to consider the proposed testimonial to Sir Henry Acland. It was resolved that the testimonial should take the form of a benefaction in connexion with the Sarah Acland Home for Nurses.

THE debate at the Pathological Society of London on the Pathology of Diphtheria will be resumed at the meeting on Tuesday, March 19th. Mr. W. Robertson will read a paper upon the Immunisation of Horses. Dr. Washbourn, Dr. Sims Woodhead, and others have promised to take part in the discussion.

MR. FRANCIS GOTCH, M.A. Oxon. (Hon.), B.Sc. Lond., F.R.S., Holt Professor of Physiology in University College, Liverpool, and late a Lecturer on Physiology at Oxford, has been elected Waynflete Professor of Physiology in the University of Oxford, in the room of Dr. J. Burdon Sanderson, now Regius Professor of Medicine.

WE learn with pleasure that Dr. R. C. A. Prior, the Senior Fellow of the Royal College of Physicians of London, is making a satisfactory recovery from the severe attack of influenza from which we reported him to be suffering last week.

MR. FREDERICK WEBB, M.R.C.S., L.S.A., of 113, Maidavale, has presented to the Medical School of St. George's Hospital the sum of £1000 to found an annual prize in bacteriology.

SIR JOSEPH LISTER has accepted the Presidency of the British Association during the meeting which will be held at Liverpool in 1896.

THE THEORY AND PRACTICE OF PROTECTIVE INOCULATIONS.

BY E. E. KLEIN, M.D., F.R.S.

DR. KLEIN delivered a lecture on this subject at the London Institution, Finsbury-circus, on Monday, March 4th. Starting with the axiom that "the more accurately we know an enemy, the more easy it is to overcome him," Dr. Klein said it nowhere more adequately applied than in the prevention and treatment of disease. Since it had been conclusively shown that communicable diseases were caused by specific parasites which elaborated within the body specific poisons called "toxines," causing the particular symptoms of the disease, it had become possible to study more accurately these causes of disease and devise better means by which the life of the parasites and the action of their toxines might be inhibited or altogether destroyed. The treatment of infectious disease had been greatly advanced, and although some of these disorders were still in a stage of generalities far-reaching changes had taken place in others. The system of antiseptic surgery discovered and applied by Sir Joseph Lister—instrumental in reducing the mortality of

surgical operations, once very high, to an almost nominal figure—and the exact knowledge we now possessed of the propagation and spread of cholera and typhoid fever by means of water, milk, and other articles of food were cases in point. Scientific medicine, in contradistinction to empirical medicine, had acted on the more rational axiom that “he who cures may be the cleverer, but he who prevents disease is the safer physician,” and had gradually unravelled the complex problems of the nature and cause of disease, and in many instances devised means of preventing communicable disease. Dr. Klein then referred to the remarkable achievements that had been made in general sanitation and in the direct prevention of disease by means of protective inoculation, of which Jenner’s discovery of vaccination was the earliest example. In all civilised countries and among all civilised peoples the protective power of vaccination against small-pox had been amply confirmed and established. Two points were particularly worth considering—(a) was vaccinia or cow-pox a modified or attenuated form of human variola? or (b) was it a separate and specifically different disease? With regard to the first point, most pathologists and sanitarians agreed with the original proposition enunciated by Jenner—namely, that vaccinia or cow-pox was a mild form of small-pox in the cow, and just as an individual who had passed through one attack of small-pox was furnished with resistance and immunity against a second attack, so also an individual who had been successfully vaccinated has practically passed through a mild attack of localised variola, was therefore possessed of immunity against a second attack, and was protected against small-pox. In some other infectious diseases—scarlet fever, measles, and whooping-cough—one attack, however mild, furnished, as a rule, immunity against a second attack. This was acquired immunity, as distinct and different from natural immunity, as, for instance, the natural immunity of most young children against typhoid fever or cholera, and of many adult persons against measles. With regard to the second point, many pathologists, while recognising the protective power of vaccinia against small-pox, did not admit that cow-pox was an attenuated form of the human small-pox, but that it was a specifically different disease. This belief was based chiefly on the many failures which experimentalists had incurred in trying to produce cow-pox in the cow by inoculation of this animal with human small-pox. It was equally true, however, that there had been many positive results, inasmuch as in a few instances there had been produced in the cow by inoculation of matter derived from the vesicles of human small-pox typical cow-pox, which on transmission to the human subject produced vaccinia and not variola, and on further transmission from human being to human being continued to produce vaccinia in all its typical characters. Thiele, Ceely, Badcock, and in more recent times Voigt, Fischer, King, Simpson, Hime, he (Dr. Klein) himself, and Copeman had had unmistakable positive results. The argument which maintained that vaccinia was of a specifically different nature from human variola was faulty for two reasons. First, as a matter of actual experience vaccination was now and then followed not simply by the production of a vaccine vesicle at the seat of insertion, but there appeared other additional vesicles even of the character of a general eruption; this, though of rare occurrence, was nevertheless a strong argument for its derivation from variola. Secondly, the “breeding true” of vaccinia in the human subject through however many transmissions and the failure of a reversion of vaccinia into variola were completely paralleled by what occurred in a disease occurring in the sheep, and was in all respects homologous to variola—namely, variola ovina or sheep-pox. Protective inoculation was used against this disease with large success in the South of France, Austria, and Germany. The lymph was “nursed” by local insertion through a succession of sheep, always producing a large local vesicle with mild constitutional symptoms. Such local inoculations had been practised over and over again, and as a general rule only at the places of insertion did a vesicle become formed; there was no general eruption, and therefore no reversion to the original type. It was clear from this that lymph derived originally from a vesicle of true variola of the sheep “bred true”—i.e., produced on transmission from sheep to sheep only local protective vesicles. If, however, this lymph were injected into the vascular system of a sheep true variola might be the result. Cheauvau, he (the speaker), and others had had cases of this kind. But while the inoculation was made by cutaneous insertion local vesicles only resulted. From this it followed that the argument because lymph derived from the cow and transmitted through

human beings did not ultimately revert to variola, but produced a local vesicle only, in no way justified the conclusion that the two diseases, variola and vaccinia, were specifically different. The conclusion to be drawn from this was that Jenner’s original contention was established. Dr. Klein then briefly referred to the work of Pasteur on anthrax and fowl cholera—a work which had been made possible by the discoveries of Koch. Satisfactory results in protective inoculations on the same lines as those pursued by Pasteur had been obtained in several—swine fever, swine erysipelas, &c.—but not in all infectious diseases. Unfortunately not in all infectious diseases did one attack protect, although a first attack furnished, for a time at any rate, a certain resistance; such was the case in diphtheria. In cases of acquired resistance or acquired immunity a condition was produced by the first attack by which the body was rendered unfit for a second attack. This sometimes happened after a mild first attack, but in other instances this only furnished a slight resistance and in still others no resistance. In these two latter cases the resistance could be increased by repetition of the mild attack and by using the second time a somewhat stronger virus and producing a somewhat stronger effect, but still only a passing one; and after many repetitions in these cases the resistance thus acquired could gradually be increased to a high degree. It had been shown, both for animals and for man, that the immunity produced by artificial inoculation of attenuated culture or acquired in the natural manner by a first attack of the disease was due to the presence in the blood of chemical substances produced in the course of the first attack; these substances were capable of neutralising the activity of the specific microbes. Moreover, it was found by Behring that the injection of blood serum of an immunised animal was capable of protecting an otherwise susceptible animal and of furnishing it with immunity, so that infection with the microbes of the particular disease was prevented. The degree of this protective or immunising power of the blood of an immunised animal stood in direct proportion to the degree of immunity or resistance which that animal had acquired by the previous injection or by the previous attack. That in diphtheria the blood of an immunised animal possessed an immunising or protective property in other animals had been fully proved, but it must be added at the same time that the protection thus produced was only of comparatively short duration. In the experiments in which the immunising and protective action of the blood serum of an animal artificially immunised against diphtheria or tetanus respectively was ascertained another important fact was elucidated by Behring, afterwards confirmed by a large number of workers—viz., that this serum not only possessed protective potency when injected into an otherwise susceptible animal, but that if injected into an animal in which the disease had already made its appearance (the disease) could be cut short and the animal would recover. The serum, therefore, acted as a curative agent. Such serum had been applied both in diphtheria by Behring and Roux, as also in tetanus by Tizzoni and Centanni, with striking success in the human subject; and the published accounts of the cases so treated in Germany, Austria, France, Italy, and England placed it beyond doubt that in a large percentage of cases the disease was cut short and even in severe cases recovery achieved. A question of great scientific interest was the manner in which the serum of animals immunised against diphtheria or tetanus acquired its protective and its curative potency. Looked at from a theoretical point of view this double action might be due to either of two things: (a) the serum might contain one substance which had both these actions, or (b) it might contain two different substances, one for each separate action. The whole subject was only at the commencement of being understood, but this much was already certain, that the work on a sound experimental basis had already been productive of good results and was likely to be productive of still greater achievements in the field of protective as well as curative practice.

MEMORANDUM ON EPIDEMIC INFLUENZA.

WE have received the following memorandum from the Local Government Board, which will be read with interest at the present time:—

Influenza became epidemic in England in the winter of

1889-90; it recurred in epidemic form in the spring of 1891, and was maintained up to June of that year; a third epidemic took place in the winter of 1891-92, and after a minor recrudescence in the spring of 1893 a fifth prevalence on a wide scale took place in the winter of 1893-94. England is now passing through a sixth epidemic period. Two detailed reports have been issued by the Board on the subject. The first was by Dr. Parsons, on the Influenza Epidemic of 1889-90, with an Introduction by Sir George Buchanan, M.D., F.R.S., the Board's medical officer at that date.¹ The second was a Further Report on Epidemic Influenza, 1889-92, by Dr. Parsons, with papers on the clinical and pathological aspects of the disease by Dr. Klein, F.R.S., and an Introduction by myself.²

A "Provisional Memorandum upon Precautions advisable at times when Epidemic Influenza threatens, or is prevalent," was also drawn up by me in January, 1892, and was issued by the Board to local sanitary authorities.

The further study made by the Medical Department as to the natural history of influenza and as to its clinical and bacteriological characteristics goes to show that it is a disease against which it is most difficult to apply measures of prevention with any substantial prospect of success.

Influenza is highly infective from person to person; its infectious quality is often manifested before the disease is fully recognised; its incubation period is one of the shortest of all infectious diseases; it varies so much in intensity that many cases are never diagnosed at all; one attack confers no marked immunity against another; and the infection is largely eliminated by means of the lungs, the sputa of the sick being invariably charged during the acute stage of the disease with its pathognomonic micro-organism. The disease calls primarily for measures of isolation and of disinfection, but there are difficulties in making any such measures universally applicable. Wherever they can be carried out the following precautions should, however, be adopted.

1st. The sick should be separated from the healthy. This is especially important in the case of first attacks in a locality or a household.

2nd. The sputa of the sick should, especially in the acute stage of the disease, be received into vessels containing disinfectants. Infected articles and rooms should be cleansed and disinfected.

3rd. When influenza threatens, unnecessary assemblages of persons should be avoided.

4th. Buildings and rooms in which many people necessarily congregate should be efficiently aerated and cleansed during the intervals of occupation.

It should be borne in mind that the liability to contract influenza, and also the danger of an attack if contracted, are increased by depressing conditions, such as exposure to cold and to fatigue, whether mental or physical. Attention should hence be paid at epidemic periods to all measures tending to the maintenance of health, such as the use of clothing of suitable warmth, and a sufficiency of wholesome food.

Persons who are attacked by influenza should at once seek rest, warmth, and medical treatment, and they should bear in mind that the risk of relapse, with dangerous complications, constitutes a chief danger of the disease.

Local Government Board,

Medical Department, March 6th, 1895.

R. THORNE THORNE.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

An ordinary meeting of the Council was held on the 7th inst., Mr. Reginald Harrison, the Senior Vice-President, being in the chair. The secretary reported the death on Feb. 19th of the President, Mr. John Whitaker Hulke, F.R.S. The following vote of condolence was passed: "The Council hereby record their deep regret at the death of their late colleague and president, Mr. John Whitaker Hulke, F.R.S., and in marking their sorrow for the loss of one so lately associated with them in all the duties and responsi-

bilities of office express their most sincere sympathy with Mrs. Hulke and the other members of the family in their affliction. The Council feel that the College has lost one of its most distinguished Fellows—one who conferred honour on the College and the whole profession of surgery, not only by his admirable skill in practice, but by his eminent position among men of science to which his varied and rare knowledge so justly entitled him. The Council also record their appreciation of Mr. Hulke's services to the College while President, and in the several offices filled by him, and their respect for his exemplary rectitude and unselfish devotion to duty."

The Senior Vice-President then declared the office of President vacant, and the Council appointed the quarterly meeting on April 4th for the election of a new president.

The Secretary reported the death, on the 4th inst., of Sir William Scovell Savory, Bart., F.R.S., past President and past member of the Council and of the Court of Examiners of the College, and the following vote of condolence was passed: "The Council hereby record their deep regret at the death of Sir William Savory, Bart., F.R.S., and desire to express their very sincere sympathy with his family in their loss. The Council gratefully remember Sir William Savory's services to the College, and the records of the Council bear witness to the many and important instances in which the best interests of the College, and of the whole surgical profession, were promoted by his energy and wisdom. The Council call to mind the many rare qualities which won for him the admiration and esteem of all who knew him, and are assured that for these, as well as for his eminence as a surgeon, his name will ever be remembered with respect and honour."

A report, dated March 4th, was read from the Committee of Management:—"The Committee of Management have, in accordance with the request of the Royal Colleges, considered the report on the examinations for the Diploma in Public Health of the inspector (Dr. G. F. Duffey) appointed by the General Medical Council. They notice in the general conclusion that the inspector states that 'the examinations give evidence on the part of candidates passing such examinations of a distinctly high proficiency, scientific and practical, in each and all branches of study which concern public health in which they are examined.' The inspector, however, in his observations, calls attention to the fact that there was no examination in bacteriology nor any clinical examination in infectious diseases. The committee desire, therefore, to point out that questions on bacteriology have frequently been given during the *visu voce* examination, and bacteriological specimens under the microscope and cultures of bacteria have been shown to candidates, and they doubt whether it is practicable to do more than test the general knowledge of the candidate in bacteriology in this manner. With regard to the remarks of the inspector in reference to the clinical examination in infectious diseases, the committee would further point out that in London the institution of such an examination would be attended with great difficulties, having regard to the large number of candidates and to the distance of the infectious diseases hospitals from the examination hall. Moreover it may be doubted if permission could be obtained for the examiners to conduct clinical examinations at the hospitals in question. It should be remembered, however, that the regulations require attendance on the practice of a hospital for infectious diseases, and this, if supplemented by a general knowledge of the subject shown by the candidate during his examination, is, in the opinion of the committee, a sufficient guarantee of his proficiency. It may also be doubted whether anything more than a superficial examination could be conducted at the bedside of patients with many of the infectious diseases."

The report was approved.

Mr. T. Pickering Pick was appointed a member of the Committee of Management and Mr. H. G. Howse a member of the Laboratories Committee in the vacancies on those committees occasioned by the death of the President.

A letter was read from Mr. Wilde on behalf of the Society of Members, which stated that the society did not wish to oppose the suggested alterations in the by-laws referring to the voting papers and the fee for the dental diploma.

A letter from the Home Secretary was read, asking Messrs. Wilde, Berger, and Moore to transmit to the Council copies of the letters from the Society of Members, and to move the Council to favour him with their observations thereon. The subject was referred to the Vice-Presidents and Mr. Bryant past President, and they were requested to draw up a reply.

¹ Report on the Influenza Epidemic of 1889-90, by Dr. Parsons, with an Introduction by the Medical Officer of the Local Government Board. (C., 6387), pp. 324. Eyre and Spottiswoode, East Harding-street, E.C.

² Further Report and Papers on Epidemic Influenza, 1889-92, with an Introduction by the Medical Officer of the Local Government Board. (C., 7051), pp. 154. Eyre and Spottiswoode, East Harding-street, E.C.

A letter was read from Mr. H. Percy Dunn forwarding, by direction of the committee of the Association of Fellows, a resolution expressing regret at the death of the President. The letter was acknowledged with the thanks of the Council.

The Senior Vice-President reported, on behalf of himself and the Junior Vice-President, the delivery of the Hunterian Oration on the 14th ult., the oration being read by Mr. T. Bryant on behalf of the late President, Mr. J. W. Hulke, who was at that date unable through illness to attend. It was resolved to request the permission of the executors of the late President to publish the oration at the expense of the College.

THE NAVY AND ARMY ESTIMATES.

WITH regard to the naval estimates, it is clear that the Government is fully alive to the vital importance of preserving our supremacy at sea, and the Admiralty have redeemed their promises as regards an increase in ships, men, and works. The medical establishments and services, in regard to which our readers are more especially interested, are provided for in Vote 3. The estimate of the sum that will be required in the year ending March 31st, 1896, to defray the expense of the medical services, including the cost of medical establishments at home and abroad, amounts to £151,400, which shows a net increase of £7500 over the estimates of last year (1894-95). The salaries and allowances amount to £35,643, a slight decrease on last year. Under the head of medicines and medical stores we find that £80,000 are required for hospital and infirmary provisions and stores, medicines, and instruments; and the contributions in aid of lock hospitals at Portsmouth, Devonport, and Hong-Kong amount to £2350. The *personnel* of the Naval Medical Service seems to have undergone little or no change since last year. There are 2 Inspectors-General of Hospitals, 8 Deputy Inspectors-General, 10 Fleet Surgeons, 6 Staff Surgeons, and 27 Surgeons, 3 head sisters, 21 sisters, and 14 dispensers. A statement showing the number, salaries, and allowances of officers and clerical staff &c. at each establishment is also given in detail in another part of the estimates.

With regard to the army, we may say that the explanatory memorandum which it is now the practice of the Secretary of State for War to issue with the Estimates greatly facilitates the comprehension of their object, scope, and arrangement, the results of the figures, and the proposed changes, and, to a certain extent, the policy that will be followed is indicated. These are matters of general interest, and we may consequently advert to a few points. Although there has been a fall in the price of supplies the saving from this source, we are told, has been absorbed by the increase of the sinking fund to repay the loan for barrack reconstruction and by the necessity for increased expenditure in order to put many old buildings into a satisfactory sanitary condition. It is hoped that a battalion will be withdrawn from Egypt during the year, but judging from the present political aspect of affairs in that country we may add that this hope does not seem likely to be realised. Passing over the proposed augmentation of artillery so as to increase the proportion of field guns to men of other arms, in which respect the British is at present dangerously below Continental armies, we come to the remarks on the report of the Inspector-General of Recruiting. Speaking generally the results are very satisfactory. The short service system, we are assured, has at length been brought to as good a state as was anticipated when it was instituted by Lord Cardwell. The army is, we think, on the whole growing in popularity as a calling and means of livelihood. We wish, however, that we could see a larger number of recruits drawn from rural instead of urban populations, and that the artisan and labouring classes, rather than the clerks of our cities and towns, enlisted more frequently than they do. The troopships hitherto at the disposal of the army, of which most medical officers have had personal knowledge and experience, are worn out and have been abolished in favour of a system of hired vessels as transports. The new system will be practically tested before any decision is finally arrived at as to whether the old troopships will be replaced by new vessels or not. The vote for works is that which shows the largest increase in the Estimates. Of the increased expenditure upon new buildings the whole of that for

barracks—viz., £58,000—is for hospital and urgent sanitary services, and even of the increase for store buildings half the sum is taken to further the scheme of the corporation of Dublin for improving the sanitary condition of that city. The progress of the works under the Barrack Act, 1890, we are told, continues to be satisfactory, the average annual expenditure being a little over £600,000. Up to the present time the sum of £3,000,000 has been authorised, and nearly £2,400,000 actually paid.

Passing to Vote 2 in the Army Estimates—that for medical establishment, pay, &c.—we find that the estimated sum required for the year ending March 31st, 1896, to defray the expense of the pay and allowances of the medical establishment and cost of medicines, &c., is £292,000, being an increase of £2000 over 1894-95. The pay &c. of the medical staff are estimated at £229,500; that of Militia medical officers and civilian practitioners amounts to £10,600; the cost of the Medical Staff Corps, nurses, clerks, and other subordinates is estimated at £37,000, and the cost of medicines &c. at £15,000, which is £1000 less than for 1894-95. A statement showing the rates of pay &c. and the allotment of the staff to the various districts and stations at home and abroad is given in Appendix No. 8. The total of the medical staff on the British establishment is 614, and that on the Indian establishment is 335. The estimated sum required for the Army Medical School, Netley, is £7,600.

Vote 14 gives the non-effective charges for officers; the total estimate for medical officers for 1895-96 amounts to £198,000.

THE PROPOSED ASSOCIATION OF QUALIFIED MEDICAL ASSISTANTS, JUNIOR MEDICAL OFFICERS, AND LOCUM-TENENTES.

A MEETING for the purpose of organising the proposed Association of Qualified Medical Assistants, Junior Medical Officers, and Locum-tenentes was held at the Examination Hall, Victoria Embankment, on Monday last, March 11th. Dr. Glover presided, and was supported by Mr. T. Howard Brocklehurst, the organising secretary, and Mr. C. Legg.

Dr. J. G. GLOVER said the cause they had met to promote was in itself a good one, and was really called for. The qualified assistants of the country were a numerous and important body, numbering perhaps 3000 or 4000. These gentlemen were of the same professional status as their principals, but in a different position. Personally, he (Dr. Glover) did not think it a dishonourable position, although an old practitioner had recently expressed the opinion that the work of breaking stones or the occupation of a navy was better than that of a qualified assistant. To be under the eye and to coöperate with a good principal was, he thought, one of the best possible things for a man just entering the profession. At the same time, the position was not a strong one and contained some disadvantages. Firstly, the qualified assistant had to contend with the competition of unqualified assistants, of whom there was a large number in England, especially in the north; secondly, they were a detached body of men, and their position could be strengthened only by organisation, which was, however, costly, and assistants were not rich. There were bodies already existing that had done much to improve the position and status of the qualified assistant. Speaking as a member of the General Medical Council he could assure them that from one-half to one-third of the time of the Council was occupied in dealing with men who employed unqualified assistants. The two medical defence unions had also done much in this direction, and he thought in taking the steps contemplated the meeting should consider how far they ought to go and how far they should combine with the existing organisations of the profession. It would be rash for them to set up as a separate organisation without duly considering the matter. The days of the unqualified assistant were over, and the qualified man should be supported, not only as a duty to the profession, but also as a duty to the public.

Mr. BROCKLEHURST announced that the following gentlemen had, in answer to the letter which appeared in THE LANCET, signified their willingness to join such an association:—Dr. W. R. Fenton, Liverpool; Mr. C. E. Moffatt,

Beverley; Mr. R. J. Farman, Longford; Dr. J. Morgan Rickey, Cork; Mr. A. Rastaub, Essex; Dr. W. Jamison, Dromore; Mr. Whitmore, Rutland; Mr. C. E. Bucknill, London; Dr. Swindells, Essex; Dr. R. L. Shaw, New Mills; Mr. E. C. Drake, Grantham; Dr. J. J. Brown, Grantham; Mr. C. J. A. Coates, Monmouth; Dr. J. W. Oliver, London; Mr. Probyn, London; Mr. W. B. Orme, London; and Dr. Marcus Quarry, London.

Mr. C. LEGG then put before the meeting the various advantages that would accrue from membership, the most important of which was the formation of a central bureau where the status of the assistant and principal could be accurately determined.

On the motion of Mr. W. B. ORME, seconded by Dr. MARCUS QUARRY, it was decided to form a committee to receive communications on the subject and to take any further steps in promoting the association.

With the usual courtesies to the Chairman the meeting was brought to a close.

We are requested to state that the subscription proposed, which is one guinea per annum, should be sent to Mr. T. W. Brocklehurst, 1, Ilchester-villas, Westham, Weymouth, Dorset, or to Mr. C. Legg, 50, Deauville-road, Clapham, London.

CIVIL RIGHTS' DEFENCE COMMITTEE.

WE have received the following report of proceedings in the Anderson appeal case from the Civil Rights' Defence Committee, with a request for its publication:—

The Anderson (Privy Council) Appeals.

The Civil Rights' Defence Committee begs to append a further list of subscribers to the Anderson (Privy Council) Appeal Fund, together with extracts from the minutes of a meeting of the committee of March 1st, 1895.

The committee is much encouraged and strengthened by the action of THE LANCET and of those branches of the British Medical Association which have voted subscriptions from the branch funds in aid of the defence entrusted to it of the professional and public rights involved in Mr. Anderson's appeals and of those branches of the British Medical Association and divisions of the London and Counties' Medical Protection Society and of those gentlemen who have kindly taken charge of lists and collected subscriptions. Time is, however, passing, and a considerable further sum—about £850—is, as has been already stated, necessary for the conduct of these appeals to the Privy Council to a satisfactory issue, and of this at least £100, but to move to the best advantage £150 are required before the special leave to appeal can be applied for. The papers and proceedings up to this stage, including many office copies from, and searches in, Trinidad, have been prepared and taken and paid for out of the funds raised, and there is at present, when all subscriptions promised are received, a balance of £45 available.

If a uniform subscription of 5s. could be obtained from one-tenth part of the medical profession of the empire, or of 2s. 6d. from one-fifth part, or of 1s. each from one-half of the profession, the defence of rights declared by all public bodies, journals, and individual members of the profession that have expressed themselves to be essential to the practice and existence of the profession need no longer be left open to question and subject to encroachment.

The committee begs to invite coöperation in organising a general uniform subscription of 5s. or 2s. 6d., and to appeal to public bodies the committee represents and to the divisions and branches of those bodies to aid in this work and to subscribe such sums as they can devote to it and as will express their sense of the importance to the profession of the rights involved.

Copies of the *interim* report will be sent to branches about to hold meetings and, as far as possible, to the members of those branches, but the committee will be very much obliged if honorary secretaries of, and of branches and divisions of, the bodies represented on the committee and members of the profession willing to assist in the collection of subscriptions will apply for such numbers of copies as they may require.

The Incorporated Medical Practitioners' Association has kindly promised to distribute at the cost of this committee the *interim* report to its members.

In continuing and renewing its appeal the committee conveys to each member of the bodies represented on it the appeal of each of those bodies to its own branches or divisions and to its own members; and, in bringing this application urgently before public bodies and individuals that have not as yet had the appeal brought to their notice, the committee earnestly invites consideration of the several votes adopted and opinions expressed by public bodies and men of high standing in the profession to the effect that, deprived of the rights which Mr. Anderson is defending, the practice of the profession as a means of livelihood would be (as it was rendered to him) impossible, and the position of medical men one of intolerable degradation.

Lord Stamford and the committee feel, therefore, the greatest confidence in appealing to every feeling of public spirit and of personal generosity for the aid necessary to enable Mr. Anderson to bring to a successful issue his difficult and meritorious defence of most valued professional and public rights.

Extract from Minutes of Meeting of March 1st, 1895.

The following extract from the proceedings of the Victoria Branch was laid upon the table:—

"The hon. secretary read a letter received from England, asking for assistance towards the appeal of Mr. Anderson of Trinidad to the Privy Council. An appeal is being made to the Privy Council, and as their decision will be law in this colony members were requested to consider the advisability of the branch voting a sum to assist the appeal.

"An expression of opinion from the branch was also asked for.

"It was resolved to vote £10 10s. towards the appeal. The branch also passed the following resolution: 'That it has been the custom in this colony, and the custom meets with the approval of the branch, for medical men when they think fit to demand payment before rendering services.'"

The following resolution of the Yorkshire branch was laid upon the table:—

"The Yorkshire branch of the British Medical Association, feeling that a great injustice has been done to Mr. Anderson, that the matter is of serious importance to the medical profession, and that it sympathises sincerely with Mr. Anderson in his difficulty, hereby resolves to contribute the sum of £10 towards his expenses."

Votes of thanks as follows were unanimously adopted:—

"That the very cordial thanks of the Civil Rights Defence Committee be tendered to the Messrs. Wakley, the Proprietors and Editors of THE LANCET, for their very powerful support and coöperation and appeal to the medical profession and for their very liberal contribution heading a special 'LANCET Fund' for the Anderson Privy Council appeals. To the Halifax (Nova Scotia), Yorkshire, and Victoria branches of the British Medical Association for expressions or resolutions of sympathy and approval and for votes from the funds of those branches to the Anderson (Privy Council) appeals.

"To the councils, secretaries, and members of the Burma, East Anglian, Lancashire, and Cheshire, South Midland, and Gloucestershire branches of the British Medical Association and to the North London and Croydon divisions of the London and Counties' Medical Protection Society for votes and expressions of sympathy, and for having taken charge of lists and raised subscriptions amongst their members.

"To the North of Ireland and Shropshire and Mid-Wales branches of the British Medical Association for their votes and expressions of sympathy with and approval of the work and objects of the committee, and of the defence by Mr. Anderson of the professional and public rights involved in his appeals, and to Dr. Barnes, Dr. C. J. Evans, Dr. J. B. Lawford, Dr. Barr, Mr. Parakh, Dr. Pruett, Dr. Lloyd Smith, Mr. Knaggs, and Mr. Whishaw for their kindly expressions of sympathy and for having taken charge of lists and collected subscriptions."

The following resolutions were unanimously adopted:—

"That a letter with the *interim* report be sent to each branch or division of the bodies represented on the committee and about to hold meetings, and as far as possible also to members of such branches or divisions, inviting their coöperation.

"That it be arranged as early as possible for a deputation, consisting of as many members of the committee as may

accept an invitation to attend, to wait upon the editor of the *Times* and other leading newspapers to invite their aid by advocating a public meeting or otherwise, and in organising a committee and raising funds to enable Mr. Anderson to carry his appeal in the case of *Anderson v. Gorrie* and others on to the House of Lords; and, in the event of failure in such appeal, to carry on the matter with a view to legislation on the subject, and to obtain an indemnity for Mr. Anderson from Parliament; that members of the Civil Rights' Defence Committee be especially urged to attend the deputation; that the president be invited to introduce the deputation; and that Mr. Anderson be invited to state his case.

"That Mr. Anderson's case, and the civil rights involved, be strongly represented to the City Guilds, and that they be asked to take part in a requisition to the Lord Mayor to convene a public meeting at the Mansion House for the purpose of organising a committee and raising funds to enable Mr. Anderson to carry his appeal in *Anderson v. Gorrie* and Others to the House of Lords."

ANDERSON (PRIVY COUNCIL) APPEAL FUND.

Public Health and Poor Law.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Stockport Urban Sanitary District.—Dr. Charles Porter, in dealing in his annual report for 1893 with the important question of infantile mortality—which, by the way, was in Stockport as high as 225 per 1000 births in 1893—makes a very interesting analysis of the returns of his district for the last five years. The main conclusions are these: the number of deaths on the first day of life is three times greater than in any succeeding day; the total number of deaths during the first week of life constitutes more than half the deaths in the first month; and the infantile mortality of the first month is nearly double that of any other month. The drift of the conclusions agrees with those given in the fifty-fourth annual report of the Registrar-General, where the distribution of mortality over the first year of life was very clearly set forth. We notice, too, in the Stockport figures that there was, as in the analysis of the Registrar-General, an arrest of diminishing mortality in the third week of life. In discussing the causes of infantile mortality Dr. Porter points out how important a factor the employment of women during the latter months of pregnancy is in producing mortality from prematurity and low vitality at birth; and he also refers to the manner in which the female workers' children are exposed in their travels to and from the caretakers' houses, thus increasing the mortality from respiratory diseases. Dr. Porter dilates upon the necessary remedial measures, and he

urges that it is more desirable to prevent female mill labour during the latter months of pregnancy than to extend the period of prohibition after confinement to three months. The existing law as regards female labour is, he considers, almost a dead letter, inasmuch as the employers are, as a general rule, ignorant of confinements amongst their employées. As a remedy he suggests the compulsory notification of birth to the employers, together with prompter registration, and the necessity for provision of properly regulated crèches. The death-rate from enteric fever in Stockport during 1893 was 0·67 per 1000, as compared with 0·24 for the thirty-three large towns; and from a study of statistics for past years Dr. Porter concludes that the disease is, to a large extent, endemic in Stockport. In reference to the prevalence of this disease in Stockport during 1893 he supplies a capital chart, which brings out well the apparent relationship of the disease to the temperature of the earth at a depth of four feet and to the diarrhoeal mortality. It seems, too, in regard to locality, that the distribution of typhoid fever and diarrhoea were in large part identical. There were 80 cases with 32 deaths from diphtheria in Stockport during 1893, numbers much in excess of previous years. Dr. Porter goes, too, very exhaustively into the distribution of the cases, and concludes, amongst other things, that the three parts of the town most affected were those built on basins of sand in which natural drainage was interfered with in 1893 owing to the configuration of the subjacent boulder clay and the unusual lowering of the ground water. In indicating the lines of future action in Stockport Dr. Porter insists upon the very great importance of converting the privy midden to the water carriage system; in fact, it would be almost impossible, he states, to over-estimate the danger to health resulting from the existing privies, which pollute the air and soil, and are beds for the development of disease germs.

St. George-the-Martyr, Southwark, Urban Sanitary District.—Dr. F. J. Waldo, in his annual report for 1893, again refers to the important part played by unregulated Salvation Army and other shelters in the dissemination of small-pox; and in illustration of this he supplies the following table, taken from Dr. Long's report to the Metropolitan Asylums Board, showing the number of patients admitted to the hospital ships who traced their infection to various shelters:—

	December, 1892.	January, 1893.	February.	March.	April.	May.	June.	July.	Totals.
Salvation Army shelters:—									
(a) Blackfriars—St. George's Southwark	—	—	3	3	6	16	3	—	31
(b) Lisson-grove, Edgware-rd., Marylebone	3	2	3	8	11	5	—	—	32
(c) Horseferry-rd., Westminster	—	—	1	7	5	1	—	—	14
(d) Others...	1	2	5	6	8	—	1	—	23
Free shelters generally	—	1	4	2	3	—	—	—	10
Totals	4	5	16	26	33	22	4	—	110

Dr. Waldo adds that in so far as the south of London is concerned he estimates that small-pox was spread in 1893 by the Blackfriars shelter to a much greater extent than the figures in Dr. Long's table appear to warrant; and he repeats his recommendation that Salvation Army and other shelters should be under the same restrictions as common lodging houses. The shelter with which Dr. Waldo is more particularly concerned has, he states, been recently enlarged so as to accommodate 500 persons in the 1d. division, 288 in the 2d. bunk dormitory, and 40 in the 3d. cubicle dormitory. The minimum cubic space allotted to each adult in the 1d. division is 90 cubic feet and 6 superficial feet, allowances which, as he points out, contrast most unfavourably with common lodging-houses, workhouses, and barracks. In referring to the carrying out of the Vaccination Acts in his district, Dr. Waldo, who was apparently unable to obtain any returns as regards vaccination from the guardians, states on information derived from other sources that in no single instance during 1892 and 1893 have the guardians in question instructed their vaccination officer to prosecute defaulters; and it appears from the returns of the vaccination officer that in the year referred to there were

13·3 and 15·3 per cent. of the births not finally accounted for in respect to vaccination. As Dr. Waldo aptly remarks, the interim recommendation of the Vaccination Commission in no way absolves boards of guardians from discharging their duties under the Vaccination Acts. During 1893 he examined the water cisterns of certain model dwellings in his district. He discovered them to be "for the most part on the roofs, often imperfectly covered in, and in most cases within a few feet of the opening of the soil-pipe ventilation." In the appendix to his report Dr. Waldo reproduces the paper which he read in February, 1894, before the Sanitary Institute on the retail bakehouses of his district, which, with the discussion on it, is well worth reading.

Stretford Urban Sanitary District.—Mr. W. John Heslop reports that the death-rate of his district for 1894 was the lowest yet recorded—i.e., 13 per 1000. Measles has been added to the list of diseases notifiable in Stretford, but Mr. Heslop is apparently reserving his judgment as to its utility. The Manchester Ship Canal is reported to have been very offensive during the summer months in so far as it affects Salford.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6625 births and 7117 deaths were registered during the week ending March 9th. The annual rate of mortality in these towns, which had increased in the six preceding weeks from 18·7 to 32·9 per 1000, further rose last week to 35·0. In London the rate was as high as 41·2 per 1000, while it averaged 30·7 in the thirty-two provincial towns. The lowest rates in these towns were 16·1 in Derby, 19·2 in Blackburn, 19·6 in Leicester, 21·0 in Swansea, and 21·5 in Birmingham; the highest rates were 40·1 in Brighton, 41·2 in London, 42·8 in Halifax, 45·2 in Leicester, and 48·0 in Plymouth. The 7117 deaths included 339 which were referred to the principal zymotic diseases, against 317 and 330 in the two preceding weeks; of these, 111 resulted from whooping-cough, 73 from measles, 62 from diphtheria, 39 from diarrhoea, 30 from "fever" (principally enteric), 23 from scarlet fever, and 1 from small-pox. No fatal case of any of these diseases was recorded last week in Blackburn; in the other towns they caused the lowest death-rates in West Ham, Croydon, Huddersfield, Gateshead, and Leicester; and the highest rates in Manchester, Salford, Bolton, and Newcastle-upon-Tyne. The greatest mortality from measles occurred in Plymouth, Bolton, Manchester, Sheffield, and Newcastle-upon-Tyne; and from whooping-cough in Norwich, Oldham, and Halifax. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 62 deaths from diphtheria included 34 in London, 6 in Liverpool, 4 in Birkenhead, 3 in Salford, and 3 in Birmingham. A fatal case of small-pox was registered in Derby, but not one in London or in any other of the thirty-three large towns. There were 54 cases of small-pox under treatment in the Metropolitan Asylum Hospitals on Saturday last, the 9th inst., against 67, 75, and 68 at the end of the three preceding weeks; 8 new cases were admitted during the week, against 18, 19, and 8 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1619, against 1657, 1658, and 1621 on the three preceding Saturdays; 141 new cases were admitted during the week, against 159, 152, and 143 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had increased from 324 to 1448 in the six preceding weeks, were 1366 last week, and were as many as 842 above the corrected average. The causes of 126, or 1·8 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Nottingham, Oldham, Bradford, Leeds, and in seven other smaller towns; the largest proportions of uncertified deaths were registered in Brighton, Birmingham, Leicester, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased from 23·9 to 42·8 per 1000 in the five preceding weeks, declined to 40·9 last week, but was 5·9 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight

Scotch towns ranged from 28.5 in Greenock and 30.9 in Perth to 43.9 in Glasgow and 44.5 in Edinburgh. The 1180 deaths in these towns included 72 which were referred to measles, 39 to whooping-cough, 14 to diarrhoea, 8 to diphtheria, 6 to scarlet fever, 3 to small-pox, and 2 to "fever." In all, 144 deaths resulted from these principal zymotic diseases, against 118 and 115 in the two preceding weeks. These 144 deaths were equal to an annual rate of 5.0 per 1000, which was 3.3 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 54 and 51 in the two preceding weeks, rose again to 72 last week, of which 30 occurred in Edinburgh, 20 in Aberdeen, 11 in Glasgow, and 7 in Leith. The deaths referred to whooping-cough, which had been 36 and 30 in the preceding two weeks, increased to 39 last week, and included 31 in Glasgow. The 8 fatal cases of diphtheria exceeded the number recorded in any recent week, and included 3 in Edinburgh and 2 in Aberdeen. The deaths from scarlet fever, which had been 4 and 10 in the two preceding weeks, declined to 6 last week, of which 4 occurred in Glasgow. Of the 3 fatal cases of small-pox 2 were registered in Edinburgh and 1 in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 345, 517, and 544 in the three preceding weeks, declined to 463 last week, but exceeded by as many as 350 the number in the corresponding week of last year. The causes of 82, or nearly 7 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 35.1 and 32.7 per 1000 in the two preceding weeks, rose again to 48.8 during the week ending March 9th. During the past ten weeks of the current quarter the death-rate in the city has averaged 34.6 per 1000, against 25.7 in London and 28.6 in Edinburgh. The 327 deaths registered in Dublin during the week under notice showed an increase of 108 upon the number in the previous week, and included 14 which were referred to the principal zymotic diseases, against numbers declining from 19 to 6 in the four preceding weeks; of these, 5 resulted from small-pox, 5 from "fever," 3 from whooping-cough, 1 from diarrhoea, and not one either from measles, scarlet fever, or diphtheria. These 14 deaths were equal to an annual rate of 2.1 per 1000, the zymotic death-rate during the same period being 1.7 in London and 7.6 in Edinburgh. The fatal cases of small-pox, which had declined from 8 to 4 in the three preceding weeks, rose again to 5 last week. The 5 deaths referred to "fever" were all certified as enteric, and exceeded the number recorded in any recent week. The 3 fatal cases of whooping-cough also exceeded recent weekly numbers. The 327 deaths in Dublin last week included 64 of infants under one year of age, and 112 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons exceeded those recorded in any recent week. Four inquest cases and 4 deaths from violence were registered; and 108, or nearly a third, of the deaths occurred in public institutions. The causes of 28, or more than 8 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING FEBRUARY, 1895.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during February in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious diseases in the metropolis during last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 5.9 per 1000 of the population, estimated at 4,392,346 persons in the middle of this year. In the three preceding months the rates had been 9.5, 8.4, and 7.0 per 1000 respectively. Among the various sanitary areas the rates were considerably below the average in Hammersmith, Westminster, St. Martin-in-the-Fields, Strand, City of London, and St. Saviour Southwark; while they showed the largest excess in Marylebone, Islington, St. Luke, Limehouse, Rotherhithe, and Greenwich. The prevalence of small-pox in London showed a slight increase during February, 48 cases being notified during the month, including 34 in Marylebone and 3 in Holborn sanitary areas. The Metropolitan Asylum Hospitals contained 66 small-pox patients at the end of February,

against 16 and 51 at the end of the two preceding months; the weekly admissions averaged 15, against 3 and 10 in the two preceding months. The prevalence of scarlet fever in London showed a slight increase upon that recorded in January; this disease was proportionally most prevalent in Hampstead, Islington, St. Luke, Limehouse, Mile End Old Town, Rotherhithe, Greenwich, and Plumstead sanitary areas. The Metropolitan Asylum Hospitals contained 1569 scarlet fever patients at the end of February, against 2114, 1865, and 1633 at the end of the three preceding months; the weekly admissions averaged 141, against 208, 171, and 148 in the three preceding months. The prevalence of diphtheria in London showed a marked further decline during February; among the various sanitary areas this disease showed the highest proportional prevalence in Holborn, Bethnal-green, Limehouse, Poplar, Camberwell, Greenwich, and Plumstead. There were 461 cases of diphtheria under treatment in the Metropolitan Asylum hospitals at the end of February, against 517, 521, and 515 at the end of the three preceding months; the weekly admissions averaged 50, against 90, 93, and 71 in the three preceding months. The prevalence of enteric fever in London also showed a marked decline during the month under notice; among the various sanitary districts this disease showed the highest proportional prevalence in St. Luke, Bermondsey, and Battersea sanitary areas. Erysipelas was proportionally most prevalent in Hackney, Bethnal-green, Battersea, Wandsworth, and Plumstead sanitary areas. The 12 cases of puerperal fever notified during February included 3 in Camberwell and 2 in Poplar sanitary areas.

The mortality statistics in the accompanying table relate to the deaths of persons actually belonging to the various metropolitan sanitary areas, the deaths occurring in the institutions of London having been distributed among the different sanitary areas in which the patients had previously resided. During the four weeks ending Saturday, March 2nd, the deaths of 10,205 persons belonging to London were registered, equal to an annual rate of 30.3 per 1000, against 15.2, 17.7, and 18.3 in the three preceding months. This exceptionally high rate was principally due to the epidemic prevalence of influenza. The lowest death-rates during February in the various sanitary areas were 16.6 in Hampstead, 19.3 in Plumstead, 19.5 in Lee, 21.9 in Woolwich, 22.0 in Lewisham (excluding Penge), 22.9 in Stoke Newington, and 23.6 in Hackney; the highest rates were 38.8 in St. Saviour Southwark and in Newington, 39.0 in Limehouse, 39.7 in Marylebone, 39.8 in Westminster and in St. George-in-the-East, 42.7 in Strand, 43.6 in St. Giles, and 49.3 in St. Luke. During the four weeks of February 514 deaths were referred to the principal zymotic diseases in London; of these, 172 resulted from whooping-cough, 119 from diphtheria, 90 from measles, 50 from scarlet fever, 44 from diarrhoea, 32 from enteric fever, 1 from an ill-defined form of "fever," and 6 from small-pox. These 514 deaths were equal to an annual rate of 1.5 per 1000, against 1.8 and 1.6 in the two preceding months. No fatal case of any of these diseases was recorded last month in St. Olave Southwark; in the other sanitary areas they caused the lowest death-rates in Kensington, Fulham, Westminster, St. James Westminster, Whitechapel, and Wandsworth; and the highest rates in St. Pancras, St. Giles, Clerkenwell, Limehouse, Poplar, and Battersea. Six fatal cases of small-pox were registered in London during the month under notice, the corrected average in the corresponding periods of the ten preceding years being 12; of these 6 deaths, 5 belonged to Marylebone and 1 to Newington sanitary areas. The 90 deaths referred to measles were 53 below the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Holborn, Shoreditch, Poplar, and Lee. The 50 fatal cases of scarlet fever were 19 below the corrected average number; the mortality from this disease showed no marked excess last month in any of the sanitary areas. The 19 deaths from diphtheria were slightly below the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Limehouse, Poplar, Camberwell, and Greenwich. The 172 fatal cases of whooping-cough were as many as 128 below the corrected average number; this disease showed the highest proportional fatality in St. Pancras, St. Giles, Clerkenwell, and Limehouse sanitary areas. The 32 deaths referred to enteric fever were within 3 of the corrected average number; there was no marked excess of "fever" mortality last month in

MONTHLY ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON—FEBRUARY, 1895.

† Including deaths from enteric group.

* Including 37 cases of membranous group.

any of the sanitary districts. The 44 deaths from diarrhoea were 14 below the corrected average number. In conclusion, it may be stated that the mortality in London during the month under notice from these principal zymotic diseases was nearly 30 per cent. below the average.

Infant mortality in London during February, measured by the proportion of deaths under one year of age to registered births, was equal to 169 per 1000, and was considerably above the average. Among the various sanitary areas the lowest rates of infant mortality were recorded in St. James Westminster, Stoke Newington, Hackney, Greenwich, Lewisham, and Lee; and the highest rates in St. Giles, Strand, Holborn, Whitechapel, St. Olave Southwark, and Battersea.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

The following officers have arrived from India in the *Victoria*:—Surgeon-Lieutenant-Colonel Cleery Surgeon-Major Bourke and Surgeon-Captains Griffiths and Morris. Surgeon-Captain Hope has arrived from Malta and Surgeon-Major Sharpe from West Africa. The arrival of the following officers at the stations given against their names is reported:—Surgeon-Major Babbie and Surgeon-Captain Burnside, Malta; Surgeon-Major Clements, West Africa; Surgeon-Major Sloggett and Surgeon-Captain Mathias, Egypt. Surgeon-Major Webb has been posted to the Western district on return from foreign service; Surgeon-Major Ryan to Aldershot. Surgeon-Captain Moffatt has been transferred from Cyprus to Egypt, Surgeon-Lieutenant Collins from the Western district to Cork, and Surgeon-Major Pike has been posted to Ireland after a tour of service abroad.

ARMY MEDICAL STAFF.

Surgeon-Captain Alfred Wright is seconded for service with the Cape of Good Hope Colonial Medical Service.

INDIA AND THE INDIAN MEDICAL SERVICE.

The following appointments are announced:—Surgeon-Captain B. C. Oldham on being relieved of his appointment as Officiating Deputy Sanitary Commissioner, Metropolitan and Eastern Bengal Circle, is appointed to do general duty at the Presidency. Surgeon-Captain Narendra Prasanna Sinha, on being relieved of his appointment as Officiating Civil Surgeon of Jessore, is appointed to act as Deputy Sanitary Commissioner, Metropolitan and Eastern Bengal Circle, during the absence on deputation of Surgeon-Captain D. M. Moir, or until further orders. Brigade-Surgeon-Lieutenant-Colonel A. Cameron, Civil Surgeon, on return from leave, is posted to the Benares district. Surgeon-Major G. A. Emerson, Civil Surgeon, on return from leave, is posted to the Fatehpur district. Surgeon-Lieutenant-Colonel H. Allison, Professor of Anatomy, Medical College, Madras, is granted furlough out of India for one year. Brigade-Surgeon-Lieutenant-Colonel Moore, A.M.S., to remain in England till June 16th, on medical certificate, in extension. Surgeon-Lieutenant-Colonel Frederick Augustus Smyth to be Brigade-Surgeon-Lieutenant-Colonel, vice Brigade-Surgeon-Lieutenant-Colonel W. R. Hooper, retired.

NAVAL MEDICAL SERVICE.

Fleet-Surgeon Charles Lyon Vasey has been placed on the Retired List of his rank.

The following appointments are notified:—Staff-Surgeons: T. J. Crowley to the *Barham*; J. O'B. Williams to the *Terror*; A. M. French to the *Tourmaline*; J. B. B. Triggs to the *Boscawen*; G. D. Twigg to the *Canada*; and G. F. Wales to the *Thunderer*. Surgeons: G. T. S. Sichel to Haslar Hospital; A. H. H. Vizard to the *Excellent*, additional; O. S. Fisher to Jamaica Hospital; C. L. W. Bunton to the *Humber*; H. B. Beatty to the *Impregnable*; E. T. P. Eames to the *Wildfire*; Bernard Ley to the *Victory*; T. T. Jeans to the *Raven*; J. A. L. Campbell to the *Vivid*; W. B. Macleod to the *Sealark*; W. G. Peck to the *Pilot*; H. Spicer to the *Martin*; H. P. Jones to the *Seafarer*; F. F. Mahon to the *Liberty*; R. H. Way to the *Nautilus*; W. H. S. Stalkart to the *Edinburgh*; and A. G. W. Bowen to the *Partridge*.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain Joseph Willoughby Hodgson, 1st Devonshire Volunteer Artillery (Western Division, Royal Artillery),

to be Surgeon-Captain. Surgeon-Lieutenant Percival Macleod Yearsley, 16th Middlesex Volunteer Rifle Corps, to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

The Queen's Rifle Volunteer Brigade the Royal Scots (Lothian Regiment): John Pirie, to be Surgeon-Lieutenant. 1st (City of Dundee) Volunteer Battalion the Black Watch (Royal Highlanders): Surgeon-Captain C. Templeman resigns his commission. 2nd Volunteer Battalion the Essex Regiment: Surgeon-Major C. E. Abbott resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the battalion on his retirement.

THE EPIDEMIC OF MEASLES ON BOARD THE "BRITANNIA."

The amount of sickness on board the training-ship *Britannia* has been made the subject of considerable correspondence in the press, but with the figures before us it seems that some of the reports have been unduly sensational, although there can be no doubt that the denizens of the training-ship have been passing through a severe epidemic. On Feb. 2nd the first case of measles occurred in the person of a cadet, who brought the infection back with him from his home. He was at once isolated in sick quarters, and the usual means were taken to prevent a spread of the disease. The mischief, however, was done, for the next cases appeared in the persons of the cadets whose quarters were on either side of the first case, and from this focus the fever spread until by Feb. 22nd 51 cases were under treatment. These 51 cases represent the extent of the epidemic, and no further case has occurred since that date. As an indication of the severity of the epidemic it should be remembered that the number of cadets is 269, the ship's company numbering 220 more, so that 20 per cent. of the lads have been attacked. From the beginning systematic inspection was in no way relaxed, but the epidemic was of a severe type, the later cases particularly manifesting a great tendency to pulmonary affection. When the severity of the February we have just gone through is remembered it is not surprising that pneumonia should have appeared, and in severe form, while in a large proportion of cases the patients were suffering from catarrh before receiving the poison of measles. Three deaths have occurred, and in two of these at least a predisposing tendency to the fatal issue was present. The first fatal case occurred in the person of an English native of Jamaica, who had recently joined the training-ship, and who might be supposed to be very susceptible to the severity of an English winter, and such a winter. This poor boy died of acute meningitis. The second death occurred in the person of a senior cadet who had suffered in the previous year from rheumatic fever which had left behind it cardiac mischief. The third fatal case succumbed to acute capillary bronchitis. The Medical Department of the Navy has shown throughout a laudable anxiety to discharge its duty towards its young charges, and neither pains nor expense have been spared to remedy and arrest the evil. In addition to the permanent sick quarters on shore temporary hospitals have been formed in the gymnasiums and other places, the medical staff of the *Britannia* has been increased, and nursing assistance obtained from the Plymouth Hospital. A convalescent home has also been obtained at Kingswear for the accommodation of the cadets, and elaborate precautions taken for complete disinfection. We note with particular approbation the provision of a convalescent home on shore; for, while a ship affords an appropriate place for the education of the future officers of the Navy, it must not be forgotten that ships are more likely to become unhygienic and unhealthy by long occupation than are buildings. But the Director-General, in his report on the epidemic to Lord Spencer—a report in which the First Lord and his colleagues concurred—uses the following words: "The sanitary condition of the *Britannia* is excellent, and the ventilation of the living and sleeping decks occupied by the cadets leaves nothing to be desired." This direct testimony to the hygienic condition of the *Britannia* is very reassuring.

ARMY RECRUITING IN 1894.

The Inspector-General for Recruiting, in his report for 1894, says: "The medical inspections have been generally very strictly carried out. The number of recruits who have been passed into the service with diseases or ailments that might have been detected at the medical examination is

exceedingly small when compared with the number examined, which shows that the medical officers have performed this important, and in some places where large numbers of recruits are examined arduous, duty with care and ability." In the course of the year 61 985 men offered themselves for medical examination, and of these 40·3 per cent. were rejected. In another part of the report it is stated that "the establishment of the Medical Staff Corps is 2478 non-commissioned officers and men. This is a popular corps and easily recruited. It is somewhat over establishment."

GAOL SANITATION.

The *Times of India*, referring to the recently issued report of the Sanitary Commissioner with the Government of India, says that there were less sickness and mortality in the Indian gaols in 1893 than at any time during the past twenty years. The year was distinguished by a large decrease in mortality generally and by a marked decline in that from cholera, fever, and small-pox. The ratio of admissions into hospital had also fallen greatly. The Sanitary Commissioner states that the death-rate of 25 per 1000 for the year is the lowest of which he can find record. The complete statistics for all the gaols have only been recorded since 1877, when the mortality was 62 per 1000, the deaths from dysentery and diarrhoea alone being 28 per 1000, whereas they are now less than 7 per 1000.

THE FEMALE HOSPITAL AT BENARES.

Some years ago a large and handsome hospital for females was built at Benares by public subscription, at a cost of 80,000 rupees, in memory of the late Maharaja of Benares. The expenditure on the maintenance of this institution has, however, usually exceeded its income. The present Maharaja, who largely subscribed to found the hospital, has now guaranteed a monthly subscription in its support equal to an endowment of a lakh of rupees, and the maintenance of an extremely useful and philanthropic institution will thus be secured to the population for a long time to come.

QUETTA DISTRICT.

The principal medical officer of the Quetta district has forwarded a report to the military authorities on the sanitary condition of the town of Quetta, in which he calls attention to the insanitary and dirty state of the narrow streets and yards, and to the overcrowding which exists—more especially in the Babu Mohalla quarter. The condition of the town and neglect of surface cleanliness are apparently such that, unless precautions be adopted, a probable outbreak of epidemic disease is anticipated.

NEW WATER SUPPLY AT MEERUT.

The scheme for a water-supply for Meerut, which has been long talked of and is much wanted, has now been completed, and it is expected that work will be begun at an early date. The proposal is to supply at first ten gallons a head, to be increased subsequently to fifteen gallons if necessary.

BACTERIOLOGY IN INDIA.

The Government of India have sanctioned a revised establishment for Professor Lingard, M.B., Imperial Bacteriologist, from April 1st, when his establishment will be moved from Poona to new premises in the hills.

His Excellency the Right Honourable the Governor of Bombay has nominated Surgeon-Major H. Martin, M.B., as medical officer on his personal staff.

The Earl of Rosebery will preside at a dinner to be held at the Whitehall Rooms, Hôtel Métropole, on Wednesday, March 20th, in connexion with the Evelina Hospital for Sick Children, Southwark.

EAST LONDON NURSING SOCIETY.—The annual meeting of the East London Nursing Society was held at the Mansion House on March 12th. Prebendary Harry Jones presided in the absence of the Lord Mayor, who was unfortunately through illness unable to be present. The principal object of the society is the nursing of the sick poor in their own homes. The visits of a trained nurse to these humble households have also the beneficial effect that her example is instructive for the family, the female members of which can thus gain some knowledge of what ought to be done in cases of illness. Canon Elwyn, Master of the Charterhouse, and the Rev. Marmaduke Hare, Rector of Bow, bore testimony to the value of the nurses' work. The accounts show a deficit of £180 and increased support is urgently needed.

Correspondence.

"Audi alteram partem."

"PARLIAMENT AND PRISON REFORM."

To the Editors of THE LANCET.

SIRS,—It must be admitted that the lengthy statement of your correspondent in THE LANCET of the 9th inst. on the maladministration of prisons and the evils of centralisation reflects somewhat seriously on the medical officers of prisons. If all these things be true, medical officers cannot divest themselves of responsibility for the existence of many grave abuses. They are armed, as you point out, with large discretionary powers, which I think they exercise to the best of their ability. The Commissioners give them a very free hand—so much so, indeed, in my own experience, that I have never known a medical recommendation for a prisoner's benefit either in respect to his diet or treatment to be ignored. But these charges are not new. They are substantially the same as those which appeared in the April number of the *Fortnightly Review* from the pen of the Rev. W. D. Morrison. Further, they are at present practically *sub judice*, as the committee appointed by the Secretary of State has not yet reported on them, so that the feverish impatience of your correspondent to pre-empt the case smacks somewhat of unfairness. Now, although I feel myself to be one of the incriminated, the tone of wholesome scepticism which marks your own leading article on the subject induces me to offer a few explanations by way of defending myself and my colleagues from this attack on us in a medical paper.

Let me premise that your correspondent's conclusions are totally at variance not only with official views, which I am prepared to hear are optimistic, but also with the facts and figures on which such views are based, and which are accessible to all in the reports of the Prison Commissioners. First, I would refer to the death-rate. Your correspondent says: "Centralisation has had disastrous results on the health of the inmates of local prisons." I need not comment on the inherent improbability of this statement, on which you imply some doubt yourself; but I would refer you to page 108 of the Report of the Prison Commissioners for the year ending March, 1894, which gives the death-rate for the past thirty-two years. Taking the average of ten years before the prisons were taken over by Government in 1878, and comparing it with the ten years after that event, I find this result: average annual death rate per 1000 of prison population, 1868-77, 11·2; average annual death-rate per 1000 of prison population, 1878-88, 8·1.

Further, for the six years since 1888 the average death-rate has fallen to 7·6. Your correspondent, however, while admitting this decrease, as shown by the figures, says that these are invalidated by two causes. First, he points to page 24 of the report, on which is found a circular sent by the Home Secretary to the magistrates, in which he calls attention to a number of cases in which persons have been committed to prison in a moribund state or suffering from serious disease, and requests more care to be taken in the way of medical examination. From this your correspondent infers that a "large number" of these cases of serious disease are not now sent to prison, or included in the death-returns. But this circular is dated March, 1885, and the mortality had declined considerably before its issue. The annual average death-rate for seven years before centralisation was 11 per 1000, while that for the seven years after centralisation, and up to the date of the circular, was only 8 per 1000. It is obvious, therefore, that the issuing of this circular has had no material effect on the figures. But your correspondent questions the accuracy of the returns for another reason. He says: "It is now more generally the practice to release prisoners who are in a dying condition before the expiration of their term." I am not prepared to deny that prisoners are more frequently released on medical grounds; but are we to look on this, too, as one of the evils of centralisation and a cruel system? The practice referred to was not in abeyance before 1878. It is no new invention. As to its effect on prison mortality statistics, I believe this to be much exaggerated; p. 92 of the last report gives the particulars of all prisoners so released during last year. Apart from pregnancy, 60 cases are shown for various causes. Out of these 60 cases 14 were removed to infectious hospitals for small-pox, 2 for typhoid fever, 1 for scarlet fever, and 1 for erysipelas; 19 were released

for tuberculosis, 5 for senile debility and chronic bronchitis, 1 for double cataract (to be operated on), 3 for Bright's disease, and 1 for stricture of urethra. Medical readers will readily understand that a large proportion of these are not likely to have died during the term of their original sentences. The total number of releases was equal to 4.1 per 1000 of the prison population. If we add half of these to the death-rate for the year under consideration, it will then amount only to 9.6, which contrasts favourably with the precentralisation death-rate of 11.2.

Your correspondent's observations on the dietary scale have a very unpractical ring about them to one who has had experience of the actual working of it since its introduction and been responsible at four different prisons in various parts of the country for supplementing it with extras to meet the special requirements of individual cases. He ignores the fact that the committee which passed the scale in 1878 were specially instructed to consider the various conditions as to climate, district, &c., to which he refers, and that it was based to a large extent on the scales in existence at the time in the local prisons then under local management. It is obvious that, for administrative purposes, some dietary scale must be in use. No scale that has ever been invented would exactly meet the physiological requirements of every individual in a large body of people. The task of framing such a scale for prisoners was one of special difficulty, and much trouble was expended over it. All this was recognised by the committee, and medical officers were consequently given full powers to deal with special cases and rectify inequalities in the working of the machinery. Without in any way claiming perfection for the scale in use, I would merely speak of it as I have found it in practice. During the past ten years my extra diet book shows on an average additions to the diet of one prisoner in every 180. This means, roughly, that the scale in existence has been sufficient, in my own experience, to meet the case of 99 in every 100 prisoners—a result which seems to me not unsatisfactory. That many prisoners should, after a course of it, leave prison weak and unfit for hard work would at first sight seem strong condemnation; but I can testify that many prisoners enter prison weak and unfit for hard work. A very large proportion are excused the tasks of hard labour which their sentences involve, many of the extra diets ordered are given to prisoners on reception, and not a few cases are admitted to the infirmary on or soon after reception. I yield to none in the desire to shield the prisoner from the consequences of his own misconduct or, it may be, misfortune; but, as the Home Secretary pointed out in the circular to which your correspondent alluded, "it must be remembered that prisons are places of penal discipline," not places where prisoners may retire to recruit their health with a view to fitting them for hard work on discharge. Your correspondent has fallen into a singular error in his figures about suicide. The facts are very simple. In the five years ending March, 1893, there were 43 cases of suicide in the prisons. Of these 2 only occurred after twelve months of imprisonment. Most people would say that 2 cases only amongst long-sentence prisoners in five years would not form a basis for any conclusions except such as to be favourable to prison treatment. The writer, however, sets to work to show the proportion between these 2 cases and the number of sentences exceeding twelve months, but in doing so he compares a five years' list of suicides with a single year's list of long sentences, and draws correspondingly startling results from the process. I must further demur entirely to the logic involved in his statement in connexion with the death-rate, that, because more than half of those who die in prison are old offenders, this indicates the fatal effects of imprisonment. Such a deduction is absurd.

For those of your readers who are disposed to accept his obviously improbable statement that the present system of administration has doubled the number of lunatics, I would venture to prescribe a grain or two of common salt. He evidently credits prisons with insane cases for which prisons are in no sense responsible. The total number of insane for the year 1893-94 was 354. They may be summarised thus: (1) found insane on reception, 282; (2) insane within one month, 17; (3) insane after one month, 55; total number received in year, 168,050. Of those under No. 3 many were reported as unstable, doubtful, or weak-minded on reception. Full particulars of each case appear on p. 110 of report. There is, indeed, no reason to believe that any increase has taken place in the

numbers which actually become insane in prison further than that which may be due to more careful diagnosis or to some general causes independent of prison treatment. It must be borne in mind that the criminal class is not of high mental standard, and it cannot fairly be compared with the general population in respect of mental stability. Large numbers of weak-minded and epileptic borderers on insanity are received every year, and special arrangements have long been in force for dealing with such cases in association wards and not in separate confinement. There are many other points I should like to have touched on, such as punishments, recidivism, &c., and in respect to which it could be easily shown that the picture is over-coloured, but I have already encroached too much on your space.

I am, Sirs, yours faithfully,

R. F. QUINTON.

March 10th, 1895.

Medical Officer, H.M. Prison, Wandsworth.

"FEVER AND SMALL-POX HOSPITALS."

To the Editors of THE LANCET.

SIRS,—I am sorry to learn in THE LANCET of March 2nd that among other things "incomplete data" furnish a reason for the writer of your annotation objecting to my evidence as to the limit of aerial diffusion of small-pox. My opinion was based upon personal observation of the facts of the case, and I did not deem it to be necessary to go into details in the report in question. The "incomplete data" to which the writer alludes are as follows. In the first place he says that I ignored the condition of the "school inmates" as to vaccination, and presumably the inmates of the adult asylum and the fever hospital as well. With regard to the fever patients the precaution to admit only those who had been vaccinated was adopted on my recommendation, but I did not on this account allow myself to suppose that patients who had not been vaccinated since infancy were proof against small-pox. On the contrary, seeing that the protective value of vaccination diminishes every year, I felt strongly that if these patients had been exposed to the infection of small-pox a large number of them would have contracted it. My object in taking this precaution was to ensure that if small-pox did break out amongst the patients they should at least have the benefits conferred by a primary vaccination. The writer makes a strong point of the "speciality of school inmates" as to vaccination, which does not appear to me to be applicable; but even if the school inmates (not to mention the inmates of the adult asylum) were as well protected from small-pox as the fever patients, it would not affect my view that if they had been exposed to the infection some of them would in all probability have caught it. The second point which the writer considers to have an "important bearing" on the case includes the stage of disease at which the patients arrived at the hospital and the proportion of convalescent to total small-pox patients. He characterises this omission as a flaw in my evidence, and gives as one of his reasons the existence of "a very general conviction that it is acute cases of small-pox, and not convalescents, that give rise to the diffusion of the infection from hospitals in which patients are aggregated." This opinion ought to receive careful attention before it is accepted, and I would suggest the following considerations, which, in my opinion, throw doubt upon its validity. In the first place, the stage of disease in which small-pox patients are most infectious has not been authoritatively determined, and considerable diversity of opinion prevails respecting the question. Secondly, the origin of outbreaks of small-pox generally proceeds from mild and unrecognised cases. And if the infection from cases so mild as to escape recognition is capable of spreading the disease, much more was the infection of patients in the stage in which they were admitted to the Gore Farm Hospital capable of disseminating the disease. I am not able to gather from the writer's remarks whether the infection of small-pox is diffusible through the air in one stage of the disease but not in another, nor could I follow him in such a view.

In conclusion, I should like to point out that the negative evidence afforded by the absence of a single case of small-pox amongst the inmates of the three institutions almost surrounding the small-pox hospital derives its value in my opinion from this very fact: positive evidence is discounted by the difficulty which attends the elimination of disturbing

causes, such as the transference of infection by personal agency.—I am, Sirs, your obedient servant,

C. E. MATTHEWS.

Fountain Hospital, Tooting, S.W., March 6th, 1895.

* * We can only assume that Dr. Matthews' letter is intended to endorse his previous one, in which he asked, "Why, then, should the question of vaccination and convalescence be used as arguments?" in a matter affecting the aerial communication of small-pox; and in which he regarded the question of convalescence as a mere "begging of the question." We must repeat that both questions are vital to the issue. We agree with Dr. Matthews that if the patients in the hospital had been really exposed to the infection of small-pox a number would have contracted it. But we doubt if it would have been a "large" number, since the patients were carefully selected, not one of them being unvaccinated. Our difficulty is in accepting the view that they were exposed to such infection as he would imply, since the generality, at least, of the small-pox patients were convalescents. And we must express our astonishment that Dr. Matthews has all along appeared to ignore the difference between the acute and the convalescent stage of small-pox in the matter of aerial conveyance. The Royal Commission appreciated the difference as far back as thirteen years ago, and on evidence that appeared to be overwhelming, and which has, so far as we are aware, never been in the slightest degree controverted. Again and again that Commission, in discussing the influence of small-pox hospitals, draw the distinction in question, and say, for example, that they are referring to "the admissions of *acute* cases," or to "cases presumably *acute*—that is, not yet *convalescent*." (The italics are ours.) We are content with the only evidence that is available on the subject, and we cannot admit that Dr. Matthews' conclusion to the effect that "the diffusion of small-pox through the air does not extend to a distance of 1000 ft." is based on data such as could alone justify it.—ED. L.

To the Editors of THE LANCET.

SIRS,—I notice in THE LANCET of Feb. 2nd, under the heading "Fever and Small-pox Hospitals," the following remarks: "To quote Dr. Matthews' own words, he has laid it down that 'the extreme limit of diffusibility' of the small-pox infection is '1000 feet.' This is based on the negative evidence that, whilst 1563 small-pox patients passed through his hospital in certain months of 1893, the inmates of a fever hospital and of the Darenth Asylum and schools, situated about 1000 feet distant, did not contract small-pox. We indicated that two points at least having an important bearing on the question had been ignored. One was the condition of the school inmates as to vaccination." I am able to give you some evidence on this point. On former occasions when small-pox patients were in the camp, say 1000 feet from the schools, all the children were as soon as possible protected by revaccination with calf lymph. In addition, very strict precautions were laid down to prevent the mingling of the attendants and servants of the schools with those of the camp. I cannot tell you what was done in 1893, as I had then left the schools, but I have thought the evidence of the precautions taken in former epidemics might prove useful as bearing on the point in question.

I am, Sirs, yours faithfully,

FLETCHER BEACH.

Formerly Medical Superintendent of the Darenth Schools for Imbecile Children.

Kingston-hill, March 7th, 1895.

THE APPOINTMENT OF MEDICAL OFFICERS IN COUNTY HOSPITALS.

To the Editors of THE LANCET.

SIRS,—A short paragraph in the Times of Feb. 25th gave a report of the annual meeting of governors of the Surrey County Hospital at Guildford on the 23rd ult., when a statement was read of its financial position and of the good results of appeals made to the county for increased subscriptions and donations. It then mentioned that a resolution

was passed for adding two medical officers to the hospital staff from outside of the town of Guildford. As the reporter gave no hint of the peculiar line of argument taken by the mover and seconder in support of their proposition, with your leave I will now supply the omission, so as to give your readers an insight into the motives which sometimes actuate the governing bodies of these useful institutions. The mover, contended that the large contributions given to the hospital by the Godalming subscribers fairly entitled them to nominate two of their resident medical men to appointments on the hospital staff, which were now to be created for them. Lord Middleton seconded the motion, and assured his hearers that, if the governors of the hospital had at the outset accepted the medical candidate then put forward by Godalming, they would have received far more liberal support in the past from that quarter of the county. I know not how your readers may view the matter, but in my opinion an unprecedented and quite indefensible step has been taken by our hospital governors, by the one part in initiating it, and by the other in acquiescing in it. In the first place, I know of no county hospital that draws the members of its medical staff from any town but that in which it is situated; and there are obvious reasons for such a restriction. Then, what is to be said of the proposal to augment the staff when the existing number is already larger than is necessary? We have now six medical officers for less than ninety beds, and I can find no instance of a hospital with a larger proportion, and but few instances, if any, with so many. But what seem to me to call most for animadversion are the terms of this new arrangement, which virtually amount to a proposal for making subscription to the hospital fund conditional on the admission of two medical men to hospital appointments. And now that the Godalming subscribers have established their right to nominate medical officers on the strength of their contributions, by parity of reasoning the other neighbouring towns of Farnham and Woking may by doubling their subscriptions acquire similar rights to make additions to the hospital staff.—I am, Sirs, your obedient servant,

Guildford, March 4th, 1895.

HENRY TAYLOR.

THE TITLE OF "DOCTOR."

To the Editors of THE LANCET.

SIRS,—At the last monthly meeting of the Faculty of Physicians and Surgeons I submitted the following motions: First, "That the attention of the Faculty having been directed to the use of the title and style of 'Doctor' by gentlemen holding only the licence of the Faculty, the clerk be instructed to communicate with such Licentiates in the name and on behalf of the Faculty, pointing out that the licence of the Faculty is a purely surgical qualification and does not legally entitle its possessor to the title of 'Doctor,' and that in any case in which it is so assumed on the strength of this qualification alone it is recommended that the practice be discontinued." Secondly, "That the attention of the Faculty having been directed to the use of the title and style of 'Doctor' by gentlemen holding only the triple qualification of the Scottish Conjoint Board, the clerk of the Faculty be instructed to communicate with such Licentiates in the name of the Faculty, pointing out that this qualification is merely a licence to practise medicine and surgery, and does not legally entitle the possessor to the title of 'Doctor,' and that in any case in which it is so assumed on the strength of this qualification alone it is recommended that the practice be discontinued." These motions being somewhat embarrassing to the Faculty were manifestly rushed, and the "previous" question was carried by a majority. Now what is the significance of this vote? I take it to be that so far as the Faculty is concerned any one of its Fellows or Licentiates may assume what title he pleases, whether he possesses it or not. It is his academic distinction or other legal qualification that a member of the medical profession puts on his door-plate or visiting card and not a popular designation. Any medical practitioner prefixing the title "Doctor" to his name in this manner implies that he is in possession of the doctorate of an university—of a doctorate which is registerable; and when he does so on the strength of mere licence to practise surgery, in my opinion, he deceives the public, and between public deception and "infamous conduct in a professional respect" the partition is surely very thin. That in these days of hyper-sensitiveness

on the part of the Medical Council, difficult often to reconcile with reasonable freedom, the present unsatisfactory state of the question of medical titles should be permitted to continue is to me not a little surprising. Lord Justice Lopes defines "infamous conduct" in the medical sense as follows: "If a medical man in pursuit of his profession has done something in respect to it which would reasonably be regarded as infamous by his professional brethren of repute, that would be evidence of infamous conduct in a professional respect. The question was not whether that which the medical man had done would be infamous if done by someone outside the medical profession. The conduct must be infamous in a professional respect." Now I venture to express the belief that most men "of repute" in the medical profession would hold the assumption of a title to which a man has no legal claim "infamous" either in or out of the profession. If the mere Licentiate of the Faculty is to be permitted to assume the title of "Doctor" on the strength of a single surgical qualification, what is to prevent the L.R.C.S. Edin., the M.R.C.S. Eng., the L.S.A., and the L.A.H. Dub., from doing the same thing, and why should men take the trouble to qualify for University graduation if the title of "Doctor" is conferred legally by a minimum qualification in surgery? For some time past in Scotland, and, I presume, also in England, the holders of the Scottish triple qualification have boldly prefixed the title of "Doctor" to their names on visiting cards and brass plates, and with respect to this the College of Physicians of Edinburgh seems to have assumed a change of front. Not many years ago it was distinctly declared in one of the bylaws of this College that its licence in no wise conferred the right to this title. In order to make sure of its present attitude in regard to the question *a propos* of the foregoing motions, I wrote to the secretary of the College requesting information on the matter, and he replied, "The College has never sanctioned the adoption by its Licentiates of designations other than those legitimately implied in the licence which it grants"; and in further reply to my query whether the title of "Doctor" was considered by the College as "legitimately implied in the licence which it grants" he stated: "I regret that I cannot add more regarding the point that you raise. Beyond what I indicated in my previous letter the College has not to my knowledge expressed itself. I fear that an interpretation of law such as you invite might be regarded as outside the scope of the College's acting." Hence the Scotch College of Physicians, in common with the Faculty of Physicians, evidently permits its Licentiates to call themselves by any title which their indelicate sense of honour allows them to assume. The kernel of the question has been so well put recently by Dr. E. H. Cartwright that doubtless you will permit me to quote the following: "A man calling himself 'Doctor' implies that he possesses a doctor's degree in some Faculty or other, and hence one who has not acquired such a degree has no absolute right to use the style. Some people there are who, while admitting that a non-university man has no right to the title 'Doctor,' maintain that an M.B. is justifiable in assuming it. It is impossible to see any grounds for such an assertion. What, I wonder, would be thought of a 'B.D.' or a 'B.C.L.' who arrogated to himself the style of the superior degree? I am inclined to think that if such a thing were done that man's university would take active steps to stop it; and yet in the Medical Faculty it is allowed to be done on all sides with impunity." But not only do registered medical men, no matter what their qualification, assume the title of "Doctor," but the country is strewn with men in possession, doubtless, of some doctorate or another who have never been within the portals of an university. I refer principally to the great body of dentists, who assume this title on the strength of a fragment of parchment from some needy German university which they have never seen, or one or other of the mushroom shops of America, whose ephemeral existence depends on the sale of degrees. Not only are these men as ignorant of Greek (a knowledge of which is required for the M.D. of the Scotch universities) as they are of Coptic; but the great bulk of them are unable to write or to speak decent English. Now Clause 40 of the Medical Act provides that if any person assume a title implying registration under this Act when he is not so registered, he renders himself liable to criminal prosecution. The assumption of the title "Doctor" by anyone practising medicine or any branch of it implies registration as such under this Act, and yet this clause is violated throughout the length and breadth of the

land with impunity. If not the letter, it is, I hold, the spirit of the Act that no practitioner of medicine should assume a title under which he is not registered, and that a violation of this should be treated as penal. As matters are at present interpreted it appears that a man, no matter what his qualification may be, providing he is registered, can assume any title he pleases. Registration thus protects dishonesty. It surely cannot be held that this is a satisfactory state of matters or that under it the public are properly safeguarded. The solution of this question is clamant, and if the universities and the licensing bodies will not act, the Medical Council should be called upon to settle what is a burning question of long duration.

I am, Sirs, yours faithfully,

D. CAMPBELL BLACK, M.D.,

Professor of Physiology in Anderson's College Medical School.
Glasgow, Feb. 20th, 1895.

"CRANIECTOMY."

To the Editors of THE LANCET.

SIRS,—In your report of the discussion at the Medical Society of London of Dr. Wallis Ord's and Mr. Cotterell's case of Craniectomy¹ I observe that I am stated to have said that in microcephalus "union of the bones followed the arrest of cerebral growth." What I did say was that "the skull was consequently small," not intending to imply that premature synostosis usually occurred. The latter view, frequently attributed to Virchow, is, I believe, not now held by him, and, as Sir George Humphry has recently stated,² there was nothing found in the nineteen idiot skulls examined by him "to suggest that the smallness of the bony cerebral envelope exerted a compressing or dwarfing influence on the brain." Indeed, according to Professor Cunningham, the skull of a typical microcephalic idiot, for many years under my care at the Royal Albert Asylum, was at the age of twenty-nine years (when he died) not fully synostosed. In the case shown at the Medical Society there was evidence of premature closure of the fontanelles and pressure symptoms, which undoubtedly justified operative measures; but I venture to question the existence of congenital microcephalus in the ordinary acceptance of the term.

I am, Sirs, yours faithfully,

Richmond-hill, March 4th, 1895.

G. E. SHUTTLEWORTH.

"CYCLING AS A CAUSE OF HEART DISEASE."

To the Editors of THE LANCET.

SIRS,—I have read with much interest Dr. G. Herschell's paper on the above subject in THE LANCET of March 2nd. I cannot, however, entirely agree with the preventive measures with which he concludes his paper.

1. *The use of a gear.*—Dr. Herschell does not, it seems to me, sufficiently explain that the gear should depend upon the strength of the rider, the weight of the machine, the kind of tyres used, and the nature of the roads over which the machine is ridden.

2. *The upright position in riding.*—I do not think that the stooping posture either "contracts the chest" or "prevents the proper expansion of the lungs," or "so interferes with the aeration of the blood as to cause the condition of breathlessness to come on more quickly."

In the first place it is surely very improbable that racing cyclists should adopt a position which contracts the chest and brings on dyspnoea. I have myself never experienced any difficulty in expanding my chest when stooping forward over the handles, nor have I ever heard such a complaint from any other cyclist. About two years ago I made some simple experiments, which show that the chest or not contracted to any practical extent. Sitting on a bicycle first in the upright posture and then bending forward in the extreme racing posture, I measured by the aid of a spirometer the maximum amount of air which I could inspire and expire. The following are the mean results in litres of four such experiments:—Sitting upright: expiration, 3.7; inspiration, 3.2. Bending forward: expiration, 4.0; inspiration, 3.5. These experiments tend to show that the capacity of the chest is increased in the forward position; this increase is due, perhaps, to the shoulders being thrown back in

¹ THE LANCET, March 2nd, 1895.

² THE LANCET, Feb. 16th, 1895.

bending forward. In riding slowly I would advocate an upright position, but in riding fast or against a head wind a cyclist by bending forward to an extent proportionate to the pace or strength of the wind materially diminishes the wind resistance and rides with considerably less effort. Dr. Herschell's last precaution—"on no account should the cyclist continue riding after he has commenced to feel short of breath" &c.—seems to me to be far too strict to be observed in practice, for under such a condition no athletic exercise could be practised.—I am, Sirs, yours faithfully,

W. J. TURRELL, M.A., M.D. Oxon.

Ilffey-road, Oxford, March 5th, 1895.

"THE TREATMENT OF INFLUENZA."

To the Editors of THE LANCET.

SIRS,—I have read Dr. Burney Yeo's letter on this subject in THE LANCET of the 2nd inst., and I am glad to see that he gives the weight of his opinion against what may be called the "over-treatment of influenza." To overload with drugs a constitution already doing hard battle with the influenza poison, to deaden, benumb, or in any way decrease the nervous sensibility with a view to relieve mere symptoms may, indeed, please your patient, but I am persuaded that it also endangers his life. Indeed, I fear many fatal cases are due to this primary mistake of treating the symptoms instead of the patient. In influenza I recognise a disease which must run a certain course, and instead of trying to abort it I endeavour to secure to the patient such circumstances as may enable him the more safely to undergo the attack. The treatment I adopt is simple enough—perhaps too simple to recommend itself to many, nevertheless I have never met with any complications worth speaking about and never lost a patient. I put the patient to bed in a sufficiently warm and airy room, gave him plenty of good beef-tea, mutton-tea, or chicken-broth—preferably beef-tea—as much cold water as he cares to sip, and a sufficiency of the liquor ammoniac acetatis every three hours to keep the skin moist, eliminate the poison, and reduce the fever. I pay no attention to the cough, headache, or the usual bodily pains, consoling my patient with the information that such pains are necessary concomitants of the disease, and that they will disappear with the fever. This I find happens in from one to three days' time, when I immediately put the patient on quinine (and occasionally on arsenic also), alcohol in some form, and plenty of raw eggs, good soups, and nourishing diet, given in small and oft-repeated quantities. I have always found my patients progress, and the only real trouble I have had is in persuading them to remain sufficiently long indoors after they consider themselves well. Among other simple remedies one physician has successfully tried bicarbonate of potash in large and frequent doses. Here the drug appears to have eliminated the poison through the kidneys, and Dr. William Robertson of Newcastle-upon-Tyne appears to have been more rapidly successful through the use of benzol—an antiseptic and bacillicide. But whatever the drug may be it appears to me that the simplest is the best, and that the chief indications are to place your patient in the most advantageous hygienic circumstances and to nurse him scientifically.

I am, Sirs, yours faithfully,

R. MAXWELL MOFFAT, M.D. St. And.

St. Heliers, Jersey, March 6th, 1895.

"THE GENERAL MEDICAL COUNCIL AND THE OBSTETRICAL SOCIETY."

To the Editors of THE LANCET.

SIRS,—I have always maintained that the onus is upon the shoulders of the proposed legislation to show the necessity for it and the reasonableness of it, so when Mr. Flemming gives up statistical evidence upon which it was admittedly based to a large extent, admits that it will not immediately or absolutely remove the unregistered practitioner, that it is doubtful whether a trained midwife in a country district would be able to earn a sufficient competence to make it worth her while to go through a comparatively expensive training, and admits that the present position of trained midwives practising chiefly amongst the poor as the employees of institutions or charities (which are usually, or I believe, always, assisted by medical men) is the best thing that could be wished for, he cannot be surprised when I say that the whole case for legislation has broken down. It appears to

me that Mr. Flemming has played the part of Balaam reversed, because his arguments cut away the ground from beneath the feet of nearly all those who supported registration before the House of Commons and of every one who has done the same in the medical and nursing papers. He came to bless the principle of registration, and he has cursed it.

I am, Sirs, your obedient servant,

[March 4th, 1895.]

LOVELL DRAGE.

"THE REMUNERATION OF THE RESIDENT OFFICERS IN ST. BARTHOLOMEW'S HOSPITAL."

To the Editors of THE LANCET.

SIRS—In the letter published in your issue on March 2nd from "An Old House Surgeon of St. Bartholomew's" there are some points that require explanation. Your correspondent says that the "resident officer is in residence for six months—say, twenty-six weeks—and pays about £1 per week for his food. Therefore in twenty-six weeks he pays £26 for food." And again, "In those six months he pays £26 and for his year's work he receives £25." Now, Sirs, if this is the experience of your correspondent, he must either have left at the end of his term of office owing a sum of money to the caterer or else the cost of living must have changed very much of late years. It will serve no useful purpose to go into details, but in my experience the cost per week came to about 28s. to 33s. It is true that lunch and dinner only amounted to about £1, but one requires more than two meals per diem in St. Bartholomew's Hospital, and the extra one with washing brings the total cost up to at least £1 10s. per week. Further, the £25 paid to the residents are paid quarterly, so that, for instance, the intern midwifery assistant and the ophthalmic house surgeon, who are appointed for six months and not for a year, receive the handsome sum of £12 10s., on which they are supposed to board themselves during their term of office. Even were the house surgeons paid while in residence, as your correspondent assumes, there would then be the first six months during which period they as juniors would have absolutely no salary at all. I would suggest that the school authorities at St. Bartholomew's Hospital should carefully consider this matter—how much better the residents are treated so far as emolument goes in other hospitals, and I feel sure that the letters which have appeared will show them as well as the governing body how unfairly some men of small means are treated under the present system.

I am, Sirs, yours faithfully,

March 11th, 1895.

FAIR PAX.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Rev. John Watson.

THE author of the book so favourably alluded to in THE LANCET of March 2nd in the annotation entitled "Our 'Gideon Grays'" is a local clergyman of whom Liverpool may be justly proud. The Rev. John Watson is well and favourably known, not only as the minister of Sefton-park Presbyterian Church, but as one of the honorary secretaries of the Hospital Sunday and Saturday Funds Committee, and it is no disparagement to former secretaries to say that Mr. Watson has brought into his secretarial duties, especially the preparation of the reports, a thoroughness and originality all his own. His appreciation of the medical profession and of the self-denying labours of its members among the poor will be recognised by his numerous countrymen who have made Liverpool their place of abode. This city has always had a large number of Scotch residents, who set a good example in thrift and industry, many rising to very prominent positions. The medical profession is now, as it has always been, well represented among them and a long list might be given of Scotch names which have enjoyed a reputation far beyond the bounds of the city.

The Assizes.

Lord Chief Justice Russell presided to-day in the Crown Court and charged the grand jury. While congratulating them on the fact that the calendar disclosed a less serious amount of crime than formerly, he observed that it was quite serious enough, there being three charges of murder, two of attempted murder, five of manslaughter, nine of stabbing,

and eight of indecent assaults on female children. His lordship noticed with satisfaction the reduction in the figures for drunkenness in the head constable's report just published, which reduction he considered due to several causes—the better supervision of public-houses, the greater care shown by licensees in refusing to serve drunken persons, the reduction of the number of public-houses, and the improvement in the intelligence and moral tone of the masses of the people.

The Use of the Knife.

Later in the day, in trying a case of wounding with intent to do grievous bodily harm, Lord Russell told the jury that they ought not to hesitate to find a prisoner guilty on the grave charge in a case like this, when they were satisfied that a knife had been used. It was one of the disgraces of this city, and one of the most serious blots on the present calendar was the number of cases in which men were charged—on slight provocation, sometimes on no provocation at all—with taking out their knives—the husband against the wife, the neighbour against the neighbour, the workman against the fellow workman. That should be put a stop to. Juries were called upon determinedly to do their duty and the judges would do theirs. This kind of offence must not be treated lightly. The offence was a danger to the peace of society, far more dangerous than many offences regarded by the law as very serious offences against property.

A Year's Inquests.

The head constable's annual report gives the following statistics in the table of inquests. The inquests were for the year 1894 918, 570 being on males and 348 on females, the difference being clearly due to the greater exposure of men and boys to accident in such a city as this. In addition to these the coroner had 542 other cases referred to him by the police and others, making a total of 1460 cases of death investigated by him during the year. The number of informal inquiries is rather less. During the year 93 post-mortem examinations were ordered, but no details of these are furnished. Among the findings of the jury, that of "Suffocated whilst in bed with parents or others" occurred in no fewer than 163 cases. The deaths of 206 males and of 113 females were caused by accident; 45 males and 16 females committed suicide; 20 males and 1 female were found drowned. The shocking verdict, "Excessive drinking," was returned in the case of 104 males and 78 females. "Natural causes" was returned in 114 cases. Most, if not all, might have been medically certified if the coroner possessed the power to seek the aid of and remunerate medical practitioners in cases where he merely holds an informal inquiry.

An Abortive Inquiry.

At the inquest held in consequence of the unfortunate case of poisoning at Skelmersdale, near Ormskirk, already mentioned in our columns,¹ the jury failed to arrive at any conclusion, and the proceedings were accordingly adjourned from Feb. 27th to March 4th. The jury being still unable to agree, the Coroner directed them to attend at the assizes in order that they might be addressed by the judge. The Lord Chief Justice charged them that if in their opinion there had been gross and culpable negligence on the part of the chemist's assistant, he was liable to be tried for manslaughter, otherwise they ought to return a verdict of misadventure. After further deliberation the jury failed to agree, and were consequently discharged.

The Death-rate.

The recent severe weather has told heavily in Liverpool, where 510 deaths were registered during the week ending on March 2nd, the rate of mortality being 52.6 per 1000. This is probably the highest death-rate ever recorded in Liverpool, and compares with 25.5 per 1000 in the corresponding week last year.

March 12th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Fatal Football Accident.

On Thursday, the 7th, an inquest was held at Hexham on the body of Mr. J. Alexander Burn, aged twenty-three years, who came by his death under very sad circumstances on

the previous Saturday. While engaged in a football match he collided with a player on the opposite side, and sustained serious injury to his spine, the precise nature of which was never ascertained. However, on the Tuesday, the fourth day after the occurrence, he died. The gentleman with whom Mr. Burn collided is a medical student at the University of Durham College of Medicine. It should be added that the father stated that his son had told him that he absolved anyone from blame. The foreman told the coroner that the jury were unanimous in recommending, through the coroner, the Rugby Union to make a revision of its rules, so that the pastime might become less dangerous. Seeing how common these very sad so-called "football accidents" are it certainly seems necessary that some alteration in the mode of playing the game should be insisted upon. If after such alterations have been made the game is still played with such serious results as now only too often arise, there can be no doubt football—an excellent game when properly played—will at no distant date deservedly fall into disrepute.

Newcastle Dispensary.

The annual meeting of this very popular and useful charity has just been held. 9567 patients were admitted by letter last year and 17,904 were casual visitors, making a total of 27,471, the largest number perhaps treated in any one year by the medical officers. The dispensary is one of the oldest and best-managed medical institutions in the north of England. It does an immense amount of work and does it well; its finances, too, are in a sound condition.

Nurses' Home and Training School.

From very small beginnings this institution has become one of considerable importance. Commenced some twenty years ago with a staff of a matron and three trained nurses, with a capital of some £200 and a subscription list of about £100 a year, it has now a staff of seventy trained nurses, ten probationers training at its expense, a matron, and an assistant matron. It has become a self-supporting institution. Last year the nurses earned £3289 1s. 9d., and in addition to their salaries, uniforms, and residence in one of the most comfortable houses in the town a bonus of £280 was divided amongst them. Nothing can better indicate the change which has come over public opinion on the nursing question than the signal success which has attended the career of this home. The neighbourhood is deeply indebted to the ladies who, as a committee, have watched over and administered the Nurses' Home and Training School. They have been fortunate in securing the services of an able matron, and it is to a very considerable extent due to the kindness and administrative capacity of Miss Ennery that the present satisfactory condition of the home is due.

Suspected Cases of Rabies at Haltwhistle.

The justices of the Petty Sessional Division of Haltwhistle, Northumberland, have issued an order that dogs "not being under the control of any person within the division are to be muzzled, and kept muzzled" until April 6th, 1895. This action has been taken in consequence of a dog being suspected of rabies.

Tragedy at Newcastle Barracks.

Thomas Turnbull, a soldier aged eighteen years, was this morning (March 11th) at the police-court charged with causing the death of a comrade, Henry Young, aged nineteen, by stabbing him in the face with a pocket-knife. On Saturday, March 9th, a quarrel took place in the barrack-square, and during it Turnbull stabbed Young in the inner corner of his right eye. Young died at about one o'clock on Sunday, and on a post-mortem examination Surgeon-Lieutenant-Colonel Hoystead found that the knife had entered the base of the brain and divided a small artery, bleeding from which gave rise to a fatal compression. Turnbull was remanded till Saturday to await the finding of the coroner's jury.

North of England Surgical Aid Society.

The annual meeting of this society was held in the board-room of the guardians, Pilgrim-street, Newcastle, under the presidency of the Vicar of Newcastle. The report showed a considerable increase of work, and if there was a slight decline in subscriptions the workmen's contributions have been kept up.

Sir J. Lowthian Bell is seriously ill at his residence, Rounton Grange, Yorks, suffering from influenza

Newcastle-upon-Tyne, March 11th.

¹ THE LANCET, March 9th, 1895.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Edinburgh Medico-Chirurgical Society.

THE ordinary meeting of this society, which was held last week, was very poorly attended, this being partly due to the prevalence of influenza keeping the profession very fully occupied with sick people, and partly, no doubt, to a reaction after the strain of three nights devoted to the discussion on Cardiac Therapeutics. Notwithstanding the smallness of the attendance a number of interesting patients and specimens were shown. Dr. McBride read a thoughtful paper on Suppuration in certain Osseous Cavities, in which he very calmly and judiciously reviewed current opinions in the light of his own long experience in the Ear and Throat Department of the Royal Infirmary, and as practising in that special department. Other communications on the billet were postponed until the society meets in May.

Health of Edinburgh.

The epidemic conditions in Edinburgh cannot be said to have abated much, if at all. Influenza is still rife, and the death-rate has during the past week gone up to 43 per 1000. Out of 225 deaths, 157 were due to diseases of the chest; and there were 2 deaths from small-pox. The intimations for the week include 8 fresh cases of small-pox, 38 of scarlet fever, and 528 of measles. Owing to the prevalence of measles amongst pupils and influenza amongst teachers, a good many schools have been shut for a short period.

Death of Dr. T. A. G. Balfour.

By the death of Dr. T. A. G. Balfour Edinburgh has lost a well-known figure. He was attending to his patients on Friday night, became ill on Saturday morning, and died on Sunday night. Dr. Balfour was seventy years of age, and had been in very active practice for forty years. He was a Fellow of, and Examiner to, the Royal College of Physicians of Edinburgh. In the College he also held the post of Curator of the Materia Medica Museum. He was a member of a medical family, one brother having been a practitioner in Portobello, and another occupied the chair of Botany in Edinburgh. Dr. Balfour took a very active interest in ecclesiastical matters. He was an elder in the Free Church of Scotland and ranged himself on the conservative and constitutional side in that denomination, and his voice was often heard in the church courts. His genial and friendly manner and kindly bearing were felt by all who came in contact with him outside the domain of ecclesiastical controversy, and many of his brethren will miss the kind and courteous greeting they always received from him.

Death of Dr. Shand.

Another figure which until recently was known to the members of the medical societies in town has gone from his place. Dr. Shand, who had formerly held a first place in Kirkcudbright as a practitioner of ability, died in Edinburgh this week at the age of seventy-two. He retired from active work years ago, after an attack which left him semi-paralysed on one side; but, a man of much determination and courage, he went about with great freedom in spite of his disabled condition.

Queen Margaret College, Glasgow.

Another set of medical wards (those of Professor John Dougall's) has been made accessible to women students in the Glasgow Royal Infirmary. The wards of two surgeons and of two physicians are thus now opened for clinical instruction to these students.

Public Health of Glasgow.

The city death-rate fell last week from 54 to 44 per 1000—an improvement due doubtless to the milder weather which now prevails.

Cremation in Glasgow.

A question having been raised as to whether the representative of a deceased person requires any legal sanction to have the remains cremated in the absence of special instructions of the deceased, the secretary of our local Cremation Society states that no such legal sanction is necessary. While in such circumstances the representative of a deceased person may dispose of the body by ordinary earth burial or cremation, with or without subsequent urn burial, no society will countenance the cremation of the remains of anyone who

was known to disapprove of cremation. In fact, one of the forms required to be filled up contains the phrase, "and I certify that the deceased expressed to me no objection (orally or in writing) to be cremated after death."

Consumption Hospitals for Scotland.

An account was given some time ago in this column of the scheme started, and now being carried out under the guidance and inspiration of one of our best-known local philanthropists, Mr. Wm. Quarrier, for the erection and maintenance of a series of hospitals for consumptives. In the course of "A Plea for Consumptive Hospitals for Scotland," a pamphlet just issued by Mr. Quarrier, the following sensible reasons are given for the building of these hospitals:—

1. Consumption is the most prevalent and most fatal disease in existence. So much is this the case that it is called the "plague of England," and I suppose it would not be unfair to say that it is equally destructive in Scotland.
 2. While the well-to-do or wealthy suffer from its ravages, consumption is essentially the poor man's disease, the outcome of poor food, poorly ventilated homes, and of overworked body and brain.
 3. Notwithstanding that the disease is so destructive, consumptive patients are often refused admittance into general hospitals on account of beds being occupied by more urgent cases, and because of the lingering nature of the disease and its almost certain fatality in its advanced stage. These very peculiarities of the disease should give the patient the strongest claim upon our sympathy.
 4. Even if the doors of the general hospitals were freely open to receive consumptive patients (and you know they are not), these institutions do not afford the necessary facilities for the proper treatment and care of such patients.
 5. While the aim is to furnish a home for consumptives and thus bring relief to the patients, undoubtedly a great benefit will be secured by affording an opportunity to physicians for the more careful study of this disease. This can be better done when a number of patients are brought together in the one building. The general public will be benefited through the education that will be given by patients who have been treated, and who have thus acquired a knowledge of how the disease may be prevented or cured.
 6. It is only by furnishing a building specially prepared for the treatment of patients afflicted with tuberculosis that satisfactory results will be obtained. In the first place, it is absolutely necessary to have a building so located that it will be free from smoke, dust, and other impurities of air incidental to city life. This is secured in the site amid the hills of Kenfrewshire.
- Mr. Quarrier contemplates having a series of six small buildings for twenty-five to thirty-five patients each, and estimates that £60,000 will be needed for completing the buildings; of this sum £12,000 have already been received. Mr. Quarrier has a board of advisers on the subject, consisting of Professor W. T. Gairdner, M.D., LL.D., F.R.S.; Professor J. G. M'Kendrick, M.D., F.R.S.; Professor Joseph Coats, M.D.; D. Yellowlees, M.D., LL.D.; James B. Russell, M.D., LL.D.; Ebenezer Duncan, M.D.; while the following medical men have also promised their practical help when required:—Professor Murdoch Cameron, M.D.; Professor D. N. Knox, M.A., M.B.; Professor John Barlow, M.D.; Professor W. L. Reid, M.D.; Dr. R. Cowan Lees, Dr. Walker Downie, Dr. Thomas Barr, Dr. T. S. Meighan, and Dr. T. Brown Henderson.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Public Health of Dublin.

At the general meeting of the Public Health Committee, which met on Tuesday, the 5th inst., Sir Charles Cameron reported that during the week ending Feb. 23rd the death-rate in the metropolitan registration district was 34.3 per 1000 persons living, the rate in the city being 39.4 per 1000. During the first eight weeks of the present year the death-rate was 0.3 per 1000 below the mean rate for the corresponding period in the previous ten years. The week ending March 2nd there were 3 deaths from influenza and 3 from small-pox. The number of cases of small-pox which occurred during the same week was 25—14 on the north side of the city and 11 on the south side. There were 61 cases of this disease under treatment in Cork-street Hospital, 34 in the Hardwicke, and 132 convalescing at Kilmaham. In the week ended Feb. 16th 56 cases of small-pox were notified, but in the following week the number fell to 27. The epidemic, which had shown great decline in the week ended Feb. 23rd, further but slightly declined last week. Up to twelve o'clock on Tuesday the cases notified for the current week numbered 5, which were all on the north side of the city.

Jervis street Hospital, Dublin.

The usual monthly meeting of the above institution was held in the board-room of the hospital on Thursday, the

7th inst. The minutes of the previous meeting were read and confirmed, and the accounts for supplies to the hospital during the past month were examined &c. The number of patients relieved during the past month amounted to 2002, of which 578 were cases from accidents. The managing committee acknowledged numerous subscriptions for the month ending February. The meeting then adjourned.

Richmond Lunatic Asylum.

An Order in Council has been issued by the Richmond Lunatic Asylum sanctioning the expenditure of £4000 to complete the erection and equipment of the new temporary buildings provided to meet the overcrowded condition of the lunatic asylum, and also the sum of £2000 for fitting up Portrane houses and offices for the accommodation of patients and to meet preliminary expenses in connexion with the erection of the new buildings.

Dublin University Calendar for 1895.

The Dublin University Calendar for 1895 has just been published by Messrs. Hodges, Figgis, and Co. I note that the number of electors on the roll of Trinity College is 4506, the returns having been brought down to the date of the last winter commencements. Efforts have been made to supervise the general information afforded in regard to the student societies &c. The subscribers to the Graduates' Tercenary Memorial have their names set forth with the amount of their benefactions. To this fund for the building of a Dublin University Union consisting of voluntary societies and organisations of the University a sum has been made available up to Dec. 31st last of £8900, and there can be no doubt that this will yet be considerably added to. In the meanwhile the board have granted as the site of the Union buildings that occupied by the present No. 29, in the Library square, and the plans for the structure are under consideration. A glance at the calendar shows that more than the usual care has been expended upon its revision.

Remarkable Case of Longevity.

A remarkable case of longevity has been brought under notice, that of a woman named Margaret McVey of Downpatrick, and on the coffin her age was stated to be 105. From other information since obtained it appears that the deceased was born at Ballykinlar in June, 1780, and was therefore 115 years old. She was married, had two children, and up to the time of her death was healthy, strong, and sensible. She remembered the battle of Ballynahinch well, and up to a short time before her death attended Ballykinlar Chapel.

The Battle of the Clubs at Cork.

We are promised a curious development in connexion with the recent prosecution of students for snow-balling. Soon after the proceedings in the police-court the *West Cork Eagle* made some comments which Mr. J. M. Lynch, one of the defendants, considers libellous, and he has accordingly caused a writ to be issued in his behalf by a solicitor.

Charge against a Poor-law Medical Officer.

The Killarney Dispensary Committee held an important investigation last week relative to a charge of neglect of duty against Mr. Paul R. Dillon. A Mrs. Sullivan, in a long letter originally addressed to the Local Government Board, stated that her son, a dispensary patient, received an injury to his head; that Mr. Dillon, on visiting him, "merely gave directions to give the patient a powder and apply mustard to his feet," but "did not examine the head of the patient, though being told that he had received a hurt on the poll"; that the following day Mr. Dillon was asked if he had brought his instruments, and "then only examined the patient's head"; that the patient died in about forty minutes after the medical man's departure; that at the inquest another medical practitioner stated he made a post-mortem examination and ascertained that "death resulted from blood being clotted on the brain, the result of a fall." Mr. Dillon's explanation to the committee gave a different aspect to the case. He stated that the messenger told him the patient had had a fit the previous night and was very bad. On arriving at the house he learned that the patient had been drinking, and at that time he heard nothing at all with regard to the patient having had a fall. As a matter of fact, the young man was actually dying from apoplexy, and treatment was ordered rather with a view to comforting the mother than in the hope that any good would result to the patient. The committee heard the evidence of several others, and

after an exhaustive investigation entirely exonerated Mr. Dillon from blame in connexion with all the charges.

Who Pays: the Guardians or the Poor-law Medical Officer?

As the remuneration of country dispensary medical officers is often so wretchedly inadequate, the result of the contest between the Midleton Poor-law guardians and Dr. Blanchard will be looked forward to with keen interest by many. Dr. O'Connell, dispensary medical officer, through ill-health was for some months incapacitated from discharging his duties, and Dr. Blanchard had been acting as his locum-tenent. The latter applied to the guardians for remuneration, but as he has not elicited a satisfactory reply he has put the matter in the hands of a solicitor, and the guardians have requested the Local Government Board to advise them as to what their legal obligations may be.

The National Calf Vaccine Institute, newly opened at Sandymount-green, near Dublin, is a welcome addition to our means of obtaining an adequate supply of unexceptionable lymph. The medical director is Mr. J. Knox Denham, and Professor McWeeney is the bacteriologist.

March 12th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Liabilities of a Traveller affected with an Infectious Disease.

EVERY perambulating Englishman is familiar with the *tracasseries* to which he may expose himself at the hands of foreign and mostly small hotel proprietors when either he himself or a member of his family has the misfortune to contract an infectious disease during his sojourn at the hostelry patronised by his party. The first thing the landlord generally does is to order the removal of the sufferer. In addition to this, damages are very commonly claimed to recoup the house for the real or imaginary prejudice caused by the presence of the patient. Now, it need hardly be said that compulsory removal may entail great danger, nor must it be forgotten that the presence of a case of scarlet fever has not unfrequently been successfully concealed from the other denizens of the establishment, in which case it is hard to appreciate the loss of credit or custom incurred by Boniface. The right of the landlord to enforce removal and the payment of damages is rarely contested by the victim who has then nothing to do but submit. Now the travelling public should know that by a judgment delivered by the Sixth Chamber of the Paris Cour d'Appel on Feb. 1st, 1895—a judgment confirmatory of the ruling of the Civil Tribunal of the Seine, dated June 30th, 1893—the position assumed by the landlord in such a contingency is untenable. In the judgment it is expressly stated that damages cannot be claimed from a visitor for the trouble and possible loss caused by the presence in the hotel of a member of that visitor's family affected with an infectious disease, provided that the medical attendant delivers a certificate to the effect that risk to life would attend removal to another house. The traveller can resist removal even if the landlord has served him with a formal notice to quit at the very onset of the illness. It is held that the illness is an accident beyond the sufferer's control, and that, further, such an unfortunate occurrence forms part and parcel of the obvious risks attending hotel-keeping. It is ruled, however, that the visitor is responsible for the expenses incurred for the cleansing and disinfection of the premises occupied by him. I have heard of extravagant charges being made at continental health-resorts after the death of a visitor whose disease was indubitably non-infectious. It is mostly at the smaller hotels that these annoying claims are made, and visitors cannot be blamed for showing fight. But when the disease is of an infectious nature it is better to come to some friendly understanding with the landlord, whose position is, after all, no enviable one under the circumstances. Should he prove recalcitrant, it is wiser to forego one's rights when possible and seek accommodation elsewhere, for an unwilling landlord and hotel staff are not exactly aids to the successful steering of a severe case of illness to recovery. It is only right that I should bear testimony to the good feeling almost invariably shown by the landlords of the best hotels here in Paris under such trying circumstances, and it is not unreasonable to expect visitors, even though they be

cognisant of the rights conferred by the above-mentioned ruling, to meet their Amphitryon half-way.

Cerebral Complications of Influenza.

Professor Cornil¹ has recently had under observation three women affected with encephalopathy of influenzal origin. In each instance recovery ensued. The first two cases were almost similar, the only difference being that in one instance the motor paralysis was on the right side and was accompanied with aphasia, whereas in the other the left side was affected and aphasia was absent. In both cases the early symptoms were identical: persistent and severe headache, followed by sudden loss of consciousness; partial coma with stertor, lasting in one case three weeks, in the other four days only; hemiparesis, retention of sensation, facial paralysis, visual troubles, inequality of the pupils, paralysis of the sphincters, and no loss of tendon reflexes. The condition might at first have been mistaken for that of acute meningitis, later for encephalitis or small hæmorrhages involving the motor centres. But recovery is against both hypotheses. The retention of sensibility, the facial paralysis and that of the sphincters, as also the ocular trouble, distinguish the condition from hysterical hemiplegia. The third case quoted was that of an hysterical woman, and the hemiplegia was accompanied with anæsthesia; but here also there were noted facial paralysis, inequality of the pupils, and aphasia, which was quite distinguishable from nervous matism, so that there could be no mistake about the diagnosis—hemiplegia complicating influenza.

Successful Laparotomy for Revolver Wound of the Abdomen in a Pregnant Woman.

M. Albarran presented to the Société de Chirurgie on the 27th ult. a young woman aged nineteen years who was admitted to the Hôpital Cochin for a bullet wound in the umbilical region at a spot four fingers' breadth from the median line. Five hours and a half after the receipt of the wound she had vomited only once—during her removal to hospital. The patient was collapsed, and there was ascertained to be some dulness at the lower part of the abdomen. A penetrating wound with internal hæmorrhage was diagnosed, and immediate laparotomy was had recourse to. During the preparations for the operation the state of the breasts led to a vaginal examination, and a pregnancy advanced to from the fourth to the fifth month was detected. Four wounds of the small intestine, necessitating the resection of twenty centimetres of the bowel, were seen directly the abdomen was opened; a fifth intestinal wound was sutured, and search for the source of hæmorrhage which continued revealed a perforation of the mesentery involving a branch of the superior mesenteric artery, which was tied. The fundus of the gravid uterus was the seat of a small wound through which protruded a loop of the umbilical cord. Wishing to terminate the operation promptly, M. Albarran resected the loop on a level with the uterine surface, the stump being returned into the uterine cavity. The abdominal incision was then quickly closed. The next day abortion took place, but nothing of interest occurred afterwards to retard complete recovery.

March 12th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Mayor of Berlin on Löffler's Bacillus.

IN America when diphtheria is prevalent the bacteriological examination of suspected cases is made in municipal laboratories free of charge. The medical club of the Luisenstadt quarter accordingly asked the municipality to follow the example of America and to make similar arrangements in Berlin. In the name of the town council the mayor answered that there was no need for this examination, as it was not yet proved that Löffler's bacillus is really the sole cause of diphtheria. In the *Medical Reform* a medical man asks ironically if the mayor would be acknowledged as an authority on bacteriological questions, and, if not, on whose advice it was that he formed his opinion on the etiology of diphtheria. The other medical journals join in blaming the mayor for his peremptory and not over-polite answer. The question will now be taken up by the "medical stores," an establishment similar to the Army and Navy Stores, where the members of the profession

can obtain medical articles at lower prices than in the ordinary shops. The directors of these stores now undertake general bacteriological examination. Practitioners who desire to have their cases investigated procure from the stores pieces of sterilised cotton-wool packed in small sterilised glasses. A bit of the cotton-wool is to be pressed on the suspected membranes, then put back into the glass, and sent in a small box to the laboratory of the stores, where the examination is performed by a specially appointed bacteriologist. The practitioner receives an answer on the following day. This system of providing for the profession an easy means of bacteriological examination in doubtful cases is very good, but as it is carried on by a private establishment the work, of course, cannot be done gratuitously. Although the charge of three marks is very moderate, it is still much too high for the poorer classes. It is, therefore, to be hoped that the mayor and town council may change their opinion as to Löffler's bacillus and provide for these investigations, a course which will be of the greatest advantage for the health of the population.

Improvements in Hospital Construction.

At the last meeting of the Berlin Hygienic Society (Gesellschaft für öffentliche Gesundheitspflege) Herr Schmieden, a leading hospital architect of Berlin, read a paper on Recent Progress made in Hospital Construction. He said that the pavilion system was now generally adopted throughout the world, even in countries like Russia, where the cold climate seemed to be an obstacle. Wood, which at first was often employed, is now completely abandoned, and only stone is used. Formerly the pavilions had but one floor, a system which requires much space; now they often consist of two, and in British hospitals even of three or four storeys, a design which not long ago would have been regarded as unhygienic. The usual ground plan is the rectangular one; there are a few exceptions where the want of space induced the architect to build circular pavilions. But this form, Herr Schmieden said, should not be generally accepted because it looks very ugly and makes a proper distribution of the buildings very difficult. Among recent buildings the new municipal hospital of Hamburg, one of the largest in the world, which contains 1500 beds and has no fewer than fifty-eight pavilions, is the most remarkable. Herr Schmieden especially mentioned the day rooms with their glass sides, which can be let down in warm weather, so that the room then forms an open balcony. All the arrangements for heating, ventilation, &c. are excellent. The operation rooms are models of their kind. They were built and furnished in accordance with the ideas of Dr. Schede, the chief surgeon, and consist only of iron, glass, and Dutch tiles, without any woodwork. Another new hospital which invites the attention both of medical men and architects is the Kaiser Friedrich Hospital for Children in Berlin. Special efforts have been made in the diphtheria pavilion to isolate the mild cases from the serious ones, and both of them from the convalescents. For this purpose the pavilion has been built in a novel way, which Herr Schmieden termed the "stage system." The building consists of three distinct parts, which are completely separated each from the other. The patients are received, according to the degree of the illness, in one of the first two wards. When the acute stage of the disease is over they come into the convalescent ward, from which they are discharged without entering any other portion of the edifice. The physician and nurses live in the diphtheria pavilion and never come to the other parts of the hospital. This is, Herr Schmieden said, of the utmost importance, as in other hospitals infection has often been conveyed by the nurses of the different wards living together. Herr Schmieden then drew the attention of the meeting to the great Policlinico Umberto in Rome, which all visitors to the last International Congress will remember. This hospital, designed for 900 patients, will cost 20,000,000 lire. The ground floor of the pavilion consists of open halls and not of sick wards, those being only on the first and second floors. This arrangement, Herr Schmieden said, is a very good one in hot climates, but it requires a great deal of space. A novel feature has been introduced in the operation room. To avoid infection the operations are performed in a sort of glass cage, so that the professor can be seen but not heard by the students who are in the room outside the cage. The architect then, speaking of England, said that the cost of hospital building was much higher there than on the Continent. In Germany a

¹ Académie de Médecine, March 5th.

sum of 4000 marks per bed is accepted as a rule, while in England 8000 marks are not thought too much. In England the rooms for the nurses, the bath-rooms, the day-rooms, &c. are furnished with a comfort nearly unknown in our general hospitals. Herr Schmieden finished his discourse with the remark that satisfactory results in hospital building can be obtained only by the collaboration of architects and physicians. The meeting was very well attended and the address greatly applauded.

March 11th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Vienna Medical Society.

At the last meeting of this society Professor Wagner spoke of the beneficial influence apparently exerted on mental alienation by an acute disease appearing in the course of it. Recovery has been observed after typhoid or intermittent fever and arthritis. The younger the patient and the shorter the period since the beginning of the mental symptoms the more advantageous is the effect of the febrile disease. Manthner has observed that atrophy of the optic nerve was cured by intercurrent small-pox. Leidesdorf experimented with transfusion of blood in cases of melancholia. In 1892 Professor Wagner saw a boy affected with muscular atrophy who contracted typhoid fever; some two months after this illness he recovered entirely from the muscular atrophy. The discovery of tuberculin provided Professor Wagner with a remedy capable of producing fever without the risk of an infectious disease. He proceeded by inducing a rise of temperature (not more than 3° F.) by means of injection, and obtained very gratifying results. The increase of body weight was a proof of the harmlessness of this remedy. The mental symptoms were never aggravated after the injections.

Death of Dr. Lorinser.

Dr. Lorinser, the late director of the Wieden Hospital, has died at the age of seventy-eight years. He was the first who proved the noxious effects of phosphorus on the maxillary bones of persons employed in match manufactories. His works, "Treatment and Care of Diseases of the Knee-joint" and "Diseases of the Vertebral Column," found universal acceptance. Dr. Lorinser, who was also an eminent botanist, held many obsolete and peculiar views; thus, he was a resolute opponent of vaccination and of mercurial therapeutics and did not believe either in hydrophobia or in the remedies used against it. In the deceased the poor lose a great benefactor, whose name is everywhere mentioned with gratitude and reverence.

The "Rettungsgesellschaft" (Humane Society).

Since Baron Mundy's death this society has been in permanent difficulties; apparently it will not long survive its promoter. Like Count Montecuculi, the present manager, Dr. Charas, exclaims: "We want money, money, and still more money." Dr. Charas is an able and very agreeable man, but the Humane Society has lost a great many friends in consequence of painful incidents which took place some ten months ago. In fact, the only hope for the society is that the municipality may assume the control of it.

March 11th.

RUSSIA.

(FROM OUR OWN CORRESPONDENT.)

The Entozoa of Finland and Russia.

DR. KLIMENKO publishes in the *Vratch* of last week a preliminary note upon the subject of the entozoa usually met with in Finland. His observations were made in the military lazaret in Helsingfors upon patients both of Finnish and Russian nationality, and both military and civil. As a result of these observations, which extended to 1427 persons, it was found that among the Finns the ova of various forms of entozoa could be demonstrated in the dejecta of as many as 29.29 per cent. of the total. Among the inhabitants of Helsingfors the percentage in whom ova could be found was as high as 29.43. This, however, is lower than what was found to be the case in St. Petersburg and Moscow, where Kessler has shown the percentages to be respectively 32.48 and 36. In

Helsingfors by far the commonest form of intestinal parasite is the tapeworm (25.2 per cent. of the total number of patients), while in St. Petersburg tapeworm ova were present in only 7.83 per cent., and in Moscow in 8.9 per cent. of the total numbers examined. The Finnish soldier is apparently more liable to worms than the Russian soldier, in the proportion of 30.71 per cent. to 27.5 per cent. In the case of the Finns, the ova met with are almost invariably those of tapeworms, round-worms being almost unknown; while among the Russian soldiery in more than half the cases the ova are those of the round-worm. Dr. Klimenko promises to publish full details of his observations later.

A New Method of spreading Syphilis.

The methods by which syphilis is spread among the peasantry in Russia are numerous, as the following incident shows. Within eighteen months Dr. Karakoz met, in one and the same village in the interior, with three cases of primary syphilitic sore upon the eyelids. This led to inquiry and it was found that there were certain old women in the village to whom anyone with a speck of dust or other foreign body in the eye was in the habit of going, and that their method of removing the foreign body was by licking it out of the eye with the tongue. Three such old women were found and examined at the dispensary; two of them were found to be healthy, but the third had syphilitic ulcers upon her tongue and elsewhere. She herself ascribed the disease in her own case to her having licked the eye of a girl, who, from the description given, was clearly syphilitic. Whether the occurrence of primary sores upon the eyelid in Russia is always, or even usually, to be ascribed to this objectionable practice it is impossible to say, but they are not uncommonly met with in that situation. Thus Dr. Poliakov, reporting a case in the *Journal of Ophthalmology* in 1893 (and his case was caused in a similar manner), stated that this was the thirty-fourth case recorded in Russian literature.

New Clinique in the University of Moscow.

A new clinique for skin diseases was opened in the Moscow Clinical Hospital on Feb. 19th (old style), a day of days in the Russian calendar, being the anniversary of the emancipation of the serfs, which took place in the year 1861. The clinique has been built with money left to the hospital by M. Solodovnikov. At the opening Professor Pospisilof, after whose plans the clinique is built, gave a brief history of the teaching of dermatology in Russia. So recently as twenty years ago there was but one clinique for skin diseases in the whole of Russia—namely, at the Army Medical Academy in St. Petersburg. In Moscow University there has for some time been a lectureship in dermatology, but for clinical purposes the university has had to use the wards of the Miasnitzkaia Hospital.

A New Russian Journal.

The new *Journal of the Society of Russian Practitioners in Memory of Pirogof* will shortly appear, as it is already announced in the *Government Gazette*. It will be edited by Professor Korsakof of Moscow, and will not have to be submitted to the censors before publication.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

The Drink Problem.

A COMMITTEE of fifty, of which the President of Columbia College is president and Dr. J. S. Billings of the United States Army is secretary, has been organised for the purpose of exhaustively studying the "drink problem." To determine its physiological and pathological aspects a circular has been issued containing the following inquiries. 1. Is the regular consumption of a moderate quantity of whisky, wine, or beer conducive to the maintenance of health and working power in any class of men? If so, in what class, and is the average quantity useful? 2. What is the quantity of whisky, wine, or beer which the average man in good health may consume daily without special risk of injuring his health? Does this vary in connexion with variations of age, of climate, or of occupation, and what are those variations? For the purpose of securing trustworthy evidence the committee are endeavouring to collect statistical information. With this object in view the following questions have been addressed to a large number of men in various

parts of the country who are above forty years of age and are engaged in mental work of a high class; the list includes the names of judges, lawyers, scientific and medical men, bankers, financiers, managers of corporations, &c.: Are you a total abstainer? Do you drink spirits, wine, or beer every day as a matter of habit? Are you aware of any chronic disturbance of your health?

Cornell Brain Association.

At a recent dinner of the alumni of Cornell University the following "form of bequest of brain" was presented from the professor of anatomy: "I now of student of Cornell University from 18 to 18 and graduated in 18 recognising the need of studying the brains of educated persons rather than those of the ignorant, criminal, or insane, in order to determine their weight, form, and fissural pattern, the correlations with bodily and mental powers of various kinds and degrees, and the influences of sex, age, and inheritance, hereby declare my wish that at my death my brain should be entrusted to the Cornell Brain Association (when that is organised) or (pending its organisation) to the curator of the collection of human brains in the museum of Cornell University, for scientific uses, and for preservation, as a whole or in part, as may be thought best. It is my hope that my family and friends may not oppose the fulfilment of this my earnest wish." The enthusiasm of the evening, however, was so great that very few of the circulars were examined by the New York alumni at their dinner, and probably not one of them was signed.

Traffic in Antitoxin.

The sale of antitoxin of a spurious quality is creating considerable discussion as well as alarm. As the United States has no central health authority, on the opinion or judgment of which the people can rely in determining the value of the remedy, deception is not difficult. In the emergency a morning paper is raising a fund for the purchase and importation of the remedy of pure quality. Antitoxin has not gained general favour, and its failures have been attributed to the lack of genuineness of the article employed.

Feb. 25th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Medical Society of Victoria

THE annual meeting of the Medical Society of Victoria was highly satisfactory. There was an exceptionally large attendance and the report of the committee stated that the attendance at all the meetings during the past year had been above the average. The treasurer's report showed a balance in favour of the society of £960. The election of office-bearers for 1895 resulted as follows:—President: Dr. Rothwell Adam. Vice-Presidents: Mr. F. D. Bird and Mr. J. T. Brett. Hon. treasurer: Dr. C. H. Mollison. Hon. librarian: Mr. J. H. Webb. Hon. secretary: Dr. A. J. Wood. Hon. auditors: Drs. Barker and G. Horne. Committee: Drs. Astles, Balls-Headley, Duncan, Grant, Gresswell, and Honman, and Messrs. Moore, J. P. Ryan, Stirling, and Syme.

Evolution and Medicine.

The retiring President, Dr. Gresswell, delivered a very long and thoughtful address on Evolution, deviating somewhat from the usual style of presidential addresses and selecting a theme which he thought required the assistance of those who deal with morbid structure operations for its complete demonstration, and which must needs react upon pathology and teach lessons to the profession. The biological arguments in favour of the doctrine of descent, as opposed to that of types, were then passed in review, with copious illustrations, which showed how intimate and profound was the speaker's knowledge of his subject. He then reminded us that comparative pathology is not necessarily evolutionary, and that care is required lest we class as instances of evolution in disease pathological phenomena presenting mere similarity among different groups of organisms. Cervical fistulae, cysts, and auricles, pinnae cysts and fistulae, harelips and cleft palates, whether in man or animals, receive, the anti-evolutionist might say, ample explanation in ontogeny without recourse to phylogeny. Similarly with retained pupillary membranes, bifid uteri in women, the development of hair on the conjunctiva or mucous membrane of the mouth of man, of talipes equino-varus, and so on.

Are there any abnormal conditions which do not receive satisfactory explanation by reference to ontogeny, but which do receive such explanation by reference to ancestral history? Dr. Gresswell suggested that the development of the anconeus quartus muscle, of the costo-coracoid fascia, and of an extra number of coccygeal vertebrae and muscles were really such conditions, but might not be universally admitted as such. He then described in detail a condition which he believed to be the only abnormality in man brought forward for explanation on phylogenetic grounds. The instance cited was that of the occurrence of an immense number of loose cartilages in the knee-joint, a reversion to what might be regarded as the primitive condition of the limb, homologous with the meta-ptyergium of the selachian, in which there is a very large number of cartilaginous elements. Again, although the cells of enchondroma myxomatodes have the characters of the cells of the notochord, and so receive explanation in ontogeny, the stellate cells of some enchondromata are not to be observed in normal structures unless we descend to selachian forms. Another fact which might be regarded as throwing light on the doctrine of descent is that in ill health there are in the main only the mechanisms of health to fall back upon. The Darwinist would say that no advantage would accrue from the perpetuation of organisms that have lost their healthy form and function, and only such mechanisms have been evolved as are sufficient to meet temporary conditions of ill health. In illustration, Dr. Gresswell took the case of pain. Those organisms would have the best chance of survival in which hurtful sensations were disagreeable, but when the mechanism beneficent in health is continued during ill health, it is detrimental to the individual. For instance, the irritation of indigestible food causes attempts at its ejection and it may be got rid of; but let inflammation be set up and the attempts at ejection continue, but aggravate the inflammation, and may even cause death. Such a result is intelligible only on the doctrine of descent. Other illustrations of the same thing were given showing that pain and the anticipation of it are sensations of generic value, consisting of many species and varieties, and that though of advantage in conditions of health, and possibly in certain diseased conditions, it becomes, when intensified, a source of danger and of death.

Small-pox at Melbourne.

The steamer *Cloncurry* arrived at Port Phillip on Jan. 28th with small-pox on board. She left Calcutta on Dec. 23rd. On Jan. 3rd one of the lascars crew sickened with small-pox, and subsequently two others. They were landed at Fremantle, West Australia, on Jan. 17th, and at that port everyone on board was vaccinated. On Jan. 19th a saloon passenger developed the disease, and becoming delirious jumped overboard. He was rescued and was none the worse for his immersion. Another case has developed since the steamer arrived, and was placed in quarantine. The passengers and crew have been revaccinated, and the ship and cargo thoroughly disinfected.

Typhoid Fever at Coolgardie.

Typhoid fever is alarmingly on the increase at the Coolgardie Goldfields, Western Australia. The Government and private hospitals are full, and steps are being taken to provide additional hospital accommodation. The sanitary arrangements are indescribable, so that with a deficient and very bad water-supply it is no wonder the disease is so rife.

Chloride of Lime in Snake-bite.

A child at Oakleigh, Victoria, was bitten by a snake, and died in spite of injections of chloride of lime and strychnine administered by Dr. Grant and Mr. Kenny.

Appointments.

The following have been appointed examiners to act with the professors and lecturers at the forthcoming medical examinations of the University of Sydney: anatomy, Dr. A. E. Mills; physiology, Professor Stirling; materia medica, Dr. A. Watson Munro; pathology, Dr. G. E. Rennie; surgery, Sir Alfred Roberts; medicine, Dr. Mackellar; medical jurisprudence, Dr. Ashburton Thompson; psychological medicine, Dr. F. Norton Manning; midwifery, Dr. James Graham; clinical medicine, Dr. Sydney Jones; clinical surgery, Dr. Fiaschi; ophthalmology, Dr. Murray Oram.—Mr. G. E. Miles, senior medical officer at Callan Park Hospital for the Insane, has been promoted to the post of medical superintendent of the Hospital for Insane at Newcastle; and Dr. R. S. Millard has been transferred to Callan Park.—Dr. G. H. Taylor has been appointed medical superintendent of the Coast Hospital at Little Bay, Sydney.

Obituary.

DANIEL HACK TUKE. M.D. HEIDELB., F.R.C.P. LOND.,
LL.D. GLASG.

IN our issue of last week we had the mournful duty of announcing the death of Dr. Hack Tuke. The following details of his life and estimate of his work will be of interest to his many friends and admirers. Daniel Hack Tuke was born at York on April 19th, 1827. He was the youngest son of Samuel Tuke and the great-grandson of William Tuke, the founder of the York Retreat, whose work in connexion with the humane treatment of the insane was on the same lines as that of Pinel in France, though the two laboured independently of each other. Dr. Tuke was delicate as a child, but he was remarkable, even in those early days, for his high spirit, which seemed to carry him through his troubles in an unexpected way. Although his schooling was often interrupted by illness he was always busy with learning of some sort or other or investigating on his own account. As an instance of this early scientific spirit may be mentioned a journey to the woods with the household cat, which he there deposited in the hope of some day re-finding it as a wild cat.

Samuel Tuke, his father, was a well-known Quaker, and his son was accordingly brought up in the family traditions, and in due time, when his health would allow, he attended as day scholar at a Friends' school. Later he went to another Friends' school at Tottenham, where he numbered among his schoolfellows some who have since become eminent. When his school education was finished he was thought to have such a legal mind that he was sent to Bradford to study law, but three months of this were quite enough for him, and he was at last allowed to begin the study of medicine, for which he longed. At about this time he seems to have held the post of steward at the York Retreat. He next came up to London, about the year 1849, entering at St. Bartholomew's Hospital. In 1852 he took the Membership of the Royal College of Surgeons of England, and in 1853 he graduated M.D. at Heidelberg. In this same year he married, and went abroad to visit the asylums of Holland, Germany, and France. In 1854 he published his first work, an account of these visits. He was now appointed visiting physician to the York Retreat and to the York Dispensary, and about this time he held the Lectureship of Psychology at the York School of Medicine. In 1857, on the death of his father, it was decided that the old family house in Lawrence-street, York, should be converted into a private asylum for ladies. This scheme, to which he looked forward with great eagerness, was frustrated by a serious attack of hæmorrhage from the lungs, which obliged him to give up practice entirely and to go south. After a year of wandering he settled in Falmouth, where he lived for fifteen years. Here, with improved health, he soon began to take active interest in town matters, such as the library, British schools, working men's club, &c., and at the same time he did much literary work, maintaining throughout the keenest interest in all things relating to psychology and the insane. In 1874 he came to London, where after a time he settled and gradually resumed practice, unable to resist the temptation so to do. Among his greatest pleasures at this time were his frequent visits to Bethlem Hospital, of which institution he subsequently became a governor; and when within the last year or two he was obliged on account of pressure of work to forego these visits

he felt it as a great trial. In 1882 his eldest son, William Samuel Tuke, died at Bournemouth. This was a terrible blow to Dr. Tuke, who had set high hopes on his medical career, which, as many of W. S. Tuke's fellow students will remember, had promised brilliantly. Dr. Tuke subsequently took up his residence at Hanwell, where the proximity of the asylum proved a great attraction to him. Here he continued to reside till the time of his death, coming up to London daily to his consulting-rooms in Welbeck-street. It was at the latter place, just after his arrival on the morning of March 2nd, that he was suddenly seized with left-sided hemiplegia. After a few hours of incomplete consciousness Dr. Tuke gradually lapsed into a coma, which lasted till his death at four o'clock of the morning of Tuesday, the 5th.

A prominent feature in Dr. Tuke's life was his indifference to the pleasures of the table; a meal would never stand between him and his work, and his family would alternately scold and smile at his ridiculous snatch luncheons of buns and glasses of ginger beer. Of Dr. Tuke's kindness of heart we think many must have a record. He was most genial and sociable by nature, and the meeting of his friends and colleagues was the chief attraction to him at social gatherings, which he invariably enjoyed. He liked to talk over matters of all kinds, but philosophical subjects and religious questions attracted him most outside the domain of medicine, and such readings and conversations were his relaxation. He was sometimes affectionately taxed by his home

circle with being sentimental; but whilst it was quite true that "sentiment" was ingrained in his fibre, as many little relics and hoardings would testify, his nature was far too simple and honest to allow of anything that savoured of the unreal. He was rather fond of poetry—Tennyson and Whittier being, perhaps, his favourite authors. He was certainly a hero-worshipper, and when engaged in this cult would take minute pains to learn all he could about the object of his affection. Hampden was thus much in his mind when he was at Oxford last year. Dr. Tuke had many devoted friends amongst young men—he was so exceedingly kind to them and would help whenever he could. A letter written by a medical friend whom he valued much described him as possessing "the gift of inspiring friendship"—it was quite true.

In endeavouring to form a true estimate of the value of the work of Dr. Hack Tuke we cannot but feel that it is difficult at present to appreciate its various parts at their just value, but yet we think it is a proper time to note the nature and quantity of what he has done, and its apparent influence on English psychiatry. Dr. Tuke had a power of continued intellectual work such as is given to very few, and which we are almost inclined to say is given most commonly to those who are not physically robust; he worked regularly till the early morning hours in his study and yet was regular in his London professional work. He always got a clear notion of the end he was aiming at, and never rested or turned till he had reached it. Steady, persistent observation with methodical recording and arranging of facts was his chief power, for, though not, as we have hinted above, without poetical feeling and sentiment, yet he was not imaginative, and he was rather a receiver and a recorder than an originator. He was the cool-eyed observer of nature, and not the far-seeing prophet. We have heard him described as a scientific sponge, taking up greedily whatever was presented to him and rendering it back uncoloured by any personal tint. His memory for facts and details was till the end extraordinary, and a case once registered in his mind was always fit to be brought out for use when the proper occasion came. We believe that he

DANIEL HACK TUKE, M.D., LL.D.

will live, if for no other work, as the historian of lunacy and its humane treatment in the nineteenth century. He knew the actors and their works personally, and in an absolutely truthful way gave the results. Dr. Tuke was not a clinical teacher, nor did he add much to the purely scientific medical knowledge of his specialty. He was a great reader of the works and observations of others and for years was a constant frequenter of the wards and the post-mortem room of Bethlem Hospital. We think that he expected to find more physical change than was generally visible to the naked eye and often left a necropsy with feelings of disappointment and yet with a hope that the time would come when the physical side of insanity would be more demonstrable. Kindly and considerate for all, his mind was a sort of balance for the weighing of scientific truth. No man and no man's work were better known all over the world, and he had visited most of the asylums in Europe and America, never losing a chance of picking up the threads which connected the present with the past. He knew the City of the Simple (Gheel) in Belgium and the secluded valley in Ireland where priest-healing had held sway. His holidays were combinations of the study of asylums with (insufficient) complete relaxation. As we have already said, he was judicial in the extreme, and though he might have strong personal feeling, by education or association, he was ever ready to hear the other side; thus, though a strong and persistent believer in non-restraint and in the humane treatment of the insane, he was quite able to see that cases might arise in which mechanical restraint might be the most humane treatment; and quite recently he expressed himself strongly that he hoped panic and sensational writing would not prevent the judicious use of baths and the pack. Dr. Tuke's earliest established work was in connexion with Sir (then Dr.) Charles Bucknill, and "Bucknill and Tuke" still holds its place as a monument of work. Later the "Influence of Mind on the Body" occupied him, and he always had a very strong personal affection for this book, which, though at its time of great value, has now been left behind. Yet it was an early record and comprised a collection of facts of great value. Though not imaginative, Dr. Tuke was a very thoughtful and careful student of hypnotism and lost no opportunity to see its legitimate development. Another special subject to which he devoted great thought and attention was moral insanity. He took a very definite position, in which he differed from some of his oldest friends, and to the end he believed in a form of insanity in which the social side was chiefly or altogether at fault, while the higher intellectual powers were intact or but slightly affected. He recently wrote a small book on the development of this idea by Prichard and Symonds.

For nearly eighteen years Dr. Hack Tuke bore the weight of editing the *Journal of Mental Science*, and no labour was too much for him to undertake and carry through for the perfect and exact editing of that journal. He not only carried out the ordinary work, but added an Index Medicus of great and lasting value. Friends believed that Dr. Tuke's hands were already full, but yet he undertook the "Dictionary of Psychological Medicine," and, knowing exactly whom to get as assistants, he produced this splendid book, which must long be the text-book for all medico-psychological subjects. Dr. Tuke's life was not devoted only to book work; he was not forgetful of the patients in and out of asylums, and was one of the originators of the "After-care" Association for patients who, having left asylums, were not fit for full work, and who needed a kind of convalescent home where they could give evidence of their real fitness to return to their ordinary work. Dr. Tuke was chairman of this association at the time of his death. For years he was a regular attendant, not only at the courts of governors of Bethlem and Bridewell Royal Hospitals, but he attended the weekly committees and knew every patient who was admitted, and thus his life was full of work and thought. Of late years with all this work he was a busy consultant whose opinion was regarded as of the first value. He did too much, but he would himself have chosen to die in harness. No one can tell the amount of good he did by that influence which is only recognised when it is lost, but the younger men in the special branch of medicine to which he was attached looked upon him as the "grand old man."

He was a representative man in the special sphere of work to which he had devoted, and even sacrificed, all his life and energies, and it is difficult to see who is to fill the gap which his death has caused amongst the practical workers in medical psychology. The simplicity of his funeral

was in keeping with that of his character, and it was felt by all his colleagues who attended on that occasion that the grave had closed over all that was mortal of a worthy, loved, and highly esteemed brother.

CHARLES H. ROBINSON, M.R.C.P., F.R.C.S. IREL.

It was with deep regret that the friends of Mr. Charles H. Robinson heard of his death, which took place at his residence, De Vesce-place, Kingstown, county Dublin, on the 1st inst., after only two days' illness. There were few men better known in Ireland in the profession, and his kindness of disposition and professional courtesy endeared him to all with whom he came in contact, whilst his practical ability was of an advanced order. Mr. Charles Robinson was born in Dublin on Jan. 19th, 1839, and was the second son of the late William T. Robinson, Comptroller of Her Majesty's Stationery Department, Ireland. He received his education chiefly at the Rev. Robert Boyle's school, Lower Leeson-street, Dublin, and his professional training in the College and Ledwich Schools, and the Adelaide and several special hospitals. He was qualified before he reached his twentieth year. He very soon afterwards went to Egypt, and on his return was appointed surgeon in the Peninsular and Oriental Steamship Company's service and on the Cape Mail steamers, where he was invariably held in the greatest esteem and respect by all on board. Returning to Ireland, he commenced practice as a physician in Dublin, where he obtained much eminence. In 1861 he became a Licentiate of the Royal College of Surgeons in Ireland, and a Fellow in 1873. In 1862 he obtained the licence of the Royal College of Physicians of Ireland, and the Membership shortly after that qualification was instituted. From 1872 to 1881 he lectured on Anatomy at the Ledwich School, in which he subsequently taught Botany and Zoology. He was for many years one of the proprietors of the Ledwich School of Medicine and Surgery and medical examiner to an insurance company. For a very long period he was one of the special correspondents in Ireland of THE LANCET. His name appears in Ziemssen's *Encyclopædia of Medicine* and his contributions to medical journals were numerous and of great merit. Among them may be mentioned: Asiatic Cholera treated by large doses of Calomel (*Dub. Med. Press*, 1866); Notes on a case of Traumatic Tetanus; Recovery (THE LANCET, Sept. 7th, 1867); Cases of Ague with Extensive Desquamation of the Cuticle (*Brit. Med. Jour.*, 1868); Remarks on Night-blindness, with notes of a case (THE LANCET, May 30th, 1868); Cases of Acute Rheumatism treated principally by the Alkaline Method (THE LANCET, June 12th, 1869); On Scarlatina sine Eruptione (THE LANCET, Feb. 12th, 1870); Herpes Circinatus treated by Local Astringents (*Practitioner*, 1870); Cases of Measles associated with Hemorrhagic Variola (*Dub. Jour. of Medical Sciences*, 1872); Rheumatic Pneumonia (*Brit. Med. Jour.*, 1876); Cirrhosis of the Liver: Alcoholic Paralysis (*Brit. Med. Jour.*, 1877); Bulbar Paralysis (THE LANCET, Oct. 19th, 1878); Hystero-Epilepsy (*Brit. Med. Jour.*, 1878).

In 1866 Mr. Robinson was appointed Examiner in Anatomy, Physiology, Materia Medica, &c., in the Royal College of Surgeons in Ireland. He was consulting surgeon to the Caragh Orphanage and a Fellow of the Royal Academy of Medicine in Ireland. He was much interested in the Masonic order. He was a member of the British Medical Association and had intended to go to the meeting in London this year. He was fifty-five years of age when he died, and, as already said, was most kind and painstaking both in his medical duties and in the ordinary affairs of life.

CHARLES EDWARD ARMAND SEMPLE, B.A., M.B. CANTAB., M.R.C.P. LOND., L.S.A.

DR. CHARLES E. ARMAND SEMPLE, whose death we briefly announced last week, took his B.A. and M.B. degrees at the University of Cambridge in 1872, and obtained the Membership of the Royal College of Physicians of London in 1894, having received his medical education at St. George's and the Middlesex Hospitals. Dr. Semple was well known as the author of numerous useful handbooks for students, and a few years back he brought out "Elements of Materia Medica and Therapeutics," a book well up to date and full of excellent illustrations. At the time of his death Dr. Semple

was secretary to the Court of Examiners at the Apothecaries' Hall, a post he had filled for several years and the responsible and multifarious duties of which he had discharged in a way that obtained much commendation. He was punctual and accurate in his work, and to his unvarying courtesy of manner all members of the examining board will readily bear witness. Dr. Semple held the post of physician to the Bloomsbury Dispensary and to the North-Eastern Hospital for Children. Originally a very strong man and active as an oarsman while at Cambridge, of late Dr. Semple had fallen much in health, and a troublesome affection of the throat and larynx that quite destroyed his splendid singing voice depressed him greatly. Though weak and ill he stuck to his work at the Apothecaries' Hall, greatly against the advice of his colleagues there, who urged upon him the necessity of rest from all labour. When last present with the Court of Examiners he expressed himself as feeling better in health, but a few days later a most severe form of influenza with alarming cardiac failure seized him, and despite all that could be done he died at his residence at Harrow on Tuesday, March 5th, leaving a widow and five young children. His numerous friends will sympathise with them in the sad loss which they have so prematurely sustained.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The death of the following eminent foreign medical man is announced:—Dr. W. Detmold, one of the oldest surgeons in the United States, he having been born in Hanover in 1808. He was the son of the King's body physician. In 1837 he went to New York, where he occupied himself mainly with orthopaedic surgery. During the civil war, however, he played an active part in the organisation of the medical department of the Northern army.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Gratz*: Dr. J. Loos has been recognised as *privat-docent* in Children's Diseases.—*Palermo*: Dr. Chiarleoni of Catania has been appointed Professor of Clinical Midwifery.—*Parma*: Dr. Corona of Sassari has been appointed Professor of Physiology.—*Prague (Bohemian University)*: Dr. Janovsky has been promoted to the Ordinary Professorship of Dermatology and Syphilography.—*Tomsk*: Dr. F. Krüger of Dorpat has been appointed Professor of Chemistry.

FOOTBALL CASUALTIES.—On Saturday last the following accidents occurred. During the progress of a match at Whalley Range, a youth, aged seventeen years, fractured his leg, and was admitted to the Manchester Royal Infirmary.—In the course of the Lancashire Championship match, at St. Helens, between the St. Helens and Oldham teams, the St. Helens full back sustained a fracture "of one of the bones in the back of the hand."

PRESENTATIONS.—Dr. Joseph Griffiths Swayne of Clifton, Bristol, on the occasion of a complimentary dinner given to him last month, was presented with a service of plate in appreciation of his fifty years' valuable work at the Bristol University College and as a medical teacher in that town. Engraved on one of the pieces of plate is the following inscription: "Presented with a service of plate to Joseph Griffiths Swayne, M.D., Emeritus Professor of Midwifery in University College, Bristol, by his colleagues, friends, and former pupils, as a mark of their personal esteem and in grateful recognition of his eminent services in the teaching of obstetric medicine and gynaecology in the Bristol Medical School and University College, Bristol, during the long period of fifty years." Dr. Swayne's work, "Obstetric Aphorisms," has been translated into eight languages.—Mr. A. Hope Walker, L.R.C.P. Lond., M.R.C.S., of Cranleigh, has been the recipient of a handsome silver-mounted gig whip from the Cranleigh ambulance classes as a small acknowledgment for his instruction on first aid.—Dr. John MacCombie, medical superintendent of the South-Eastern Hospital, New-cross-road, has been presented with his portrait by the principal officers and charge nurses in commemoration of the opening of the home for nurses, at the hospital, and as a token of their esteem.

THE DENTAL HOSPITAL OF LONDON.—The thirty-seventh annual meeting of this institution was held at the hospital on Wednesday, March 13th, Mr. Henry Harben, a vice-president, in the chair. The report, which was read, was unanimously adopted. The special appeal issued for the necessary funds to build a new hospital has realised £11,223 16s. 4d. The value of the present site is estimated at £15,000 to £20,000 (but this sum cannot be realised until the new building is erected), making together about £26,000, and as it has been estimated that the cost of the site and the new hospital will be about £40,000, there remains a balance of £14,000 to be collected, which sum the committee have no hesitation in asking the public to speedily contribute.

CHESTERFIELD HOSPITAL.—The Chesterfield and North Derbyshire Hospital appears to occupy an unusual position, inasmuch as it is, by the terms of its constitution, debarred from receiving patients in need of medical treatment, its benefits being reserved for surgical cases only. This anomaly, though upheld and defended by the governing body, has long been apparent to the townspeople, and various unsuccessful attempts have been made to remove it. In prospect of a renewal of these endeavours the governing body have published their views of the question, calling attention especially to Rule 2 of the hospital, which is as follows: "The hospital shall be open to receive only those persons who require surgical treatment; cases of disease or sickness in any form, and chronic cases, shall be excluded." They, moreover, point out that the creation of a medical department implies two additional wards, one for each sex, and further accommodation for the extra nurses and servants who would be employed. This extension is impossible from want of room on the present ground, and to raise the height of the existing buildings is inadvisable "having regard to the probability that the site has been undermined."

MANCHESTER MEDICAL SOCIETY.—A meeting of this society was held on March 6th, the President, Mr. F. A. Southam, being in the chair.—Dr. Moritz showed a case of Agglutination of the Vocal Cords. There was complete adhesion of the vocal cords occurring in a woman aged twenty-four, who came under observation six months ago suffering from great dyspnoea and aphonia. The vocal cords were then found coherent in their anterior two-thirds, but there were no other cicatrices or ulcers visible in the larynx. Some white scars, however, on the palate, the consequence of an ulceration from which the patient had suffered three years ago, pointed to the syphilitic origin of the affection. On account of the urgent dyspnoea tracheotomy was performed, and when examined a week later the glottis was found entirely occluded by the complete agglutination of the vocal cords. Though this had been incised several times and dilated with Schröter's catheters the opening always closed up again in a few days. Dr. Moritz mentioned that he intended now, after making a fresh incision, to introduce a modified O'Dwyer's tube, and if the result should not be satisfactory thyrotomy and excision of the cicatricial tissue will be performed.—Dr. Ernest S. Reynolds showed a series of thirty-three lantern slides illustrating various cases of Nervous Disease.—Dr. Leech read a paper on the Causes of Death in Pneumonia.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 5th, Dr. Adolph Bronner, Vice-President, in the chair.—Mr. Horrocks showed a specimen of Sarcoma of the Femur taken from a woman aged sixty-one.—Dr. Major showed a Cerebellum containing a large Cyst, and read notes on the case. The patient, aged eleven years, came under Dr. Major's care in September, 1894, and died on Oct. 18th. The symptoms noted were headache, vomiting, interference with power of locomotion—going on to inability to walk,—failure of sight, and emaciation. On admission into the Infirmary there were double optic neuritis, passing on to atrophy, mental apathy, and a tendency to fall backwards on standing. The knee-jerks were diminished on both sides. There was no paralysis. On post-mortem examination a cyst containing two ounces of clear fluid was found in the left cerebellar hemisphere. There were no signs of hydatid disease. Dr. Major referred to the rarity of these cases and discussed the origin of the cysts.—Mr. Althorp read notes on some cases of Cerebellar Cysts.—Dr. A. Bronner read a paper on Some Reflexes of Nasal Origin.—Dr. S. A. Shlach read a paper on Microcephalic

Idiocy, with notes on two cases, and showed photographs of the two patients. The morbid anatomy of this condition was discussed, and the propriety (or otherwise) of craniotomy was gone into. The clinical history of the two cases was fully given.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Proposed Registration of Architects.

A BILL of forty-four clauses and four schedules has been introduced into the House of Commons for the purpose of setting up a system of registration for architects, and thus enabling persons requiring professional aid in architecture to distinguish qualified from unqualified practitioners. In the first place it proposes to establish, in a manner somewhat similar to that adopted in the case of the medical profession, a General Council of Architectural Education and Registration of the United Kingdom, with branch councils for England, Scotland, and Ireland. Like the General Medical Council, this new body will have the custody of the register and draw fees for registration, and it is empowered, if it has money to spare, to apply it to the support of museums, libraries, or lectureships, or for public purposes connected with the profession of architecture, or to the promotion of learning and education in connexion with architecture. In the clause dealing with removal from the register the framers of the Bill adopt from the Medical Act the phrase "conduct infamous in a professional respect." As to the qualifying examination, it is said: "The standard of proficiency required from candidates at the said qualifying examinations shall be such as sufficiently to guarantee the possession of the knowledge and skill requisite for the efficient practice of architecture, and it shall be the duty of the General Council to secure the maintenance of such standard of proficiency." Arrangements are made in the Bill for the registration of colonial and foreign practitioners.

The Select Committee on the Unemployed.

Following out the instructions given them at the time of their appointment, this committee have presented to the House of Commons an interim report. In this document an account is given of the steps already taken by the committee to procure evidence of the distress in the country arising from want of employment and of the measures adopted for its relief, and later it is said:—

"It is abundantly clear that, while over a great part of the country no lack of employment has prevailed beyond that which might be expected as a consequence of an unusually severe winter, there is and has been during the present severe weather much grave distress, affecting workmen ordinarily in regular work, as well as those whose employment is always liable to be intermittent, and that much suffering has been caused by this distress in many parts of the country; and there are, without doubt, many places where, underlying the distress due to weather, there exists a chronic want of employment of labour which will remain in force after milder weather has opened the out-door trades. Your committee, therefore, feel that it would have been most desirable had they been able, apart from the general inquiry which you entrusted to them, to make some recommendations applicable to the present juncture. But any such recommendation must satisfy two conditions: (a) it must be immediately applicable during the remaining weeks of the winter season; (b) it must be such that Parliament might be reasonably expected to accept it, or even take it into serious consideration, without further inquiry into the facts upon which it is founded or the principle it embodies. It is with full regret that your committee find that no plan has been suggested to them which fulfils these considerations."

In these circumstances the committee propose that they should proceed with their inquiry without making any recommendation at this time.

Food and Drugs Adulteration.

The committee on this subject, which began its inquiry last year, has been reappointed. It held its first meeting on Tuesday, March 12th, when it again elected Sir Walter Foster as its Chairman, and decided to resume the examination of witnesses on Tuesday, March 19th.

HOUSE OF COMMONS.

THURSDAY, MARCH 7TH.

Dangerous Trades under the Factories Act.

Mr. Knox addressed a question to the Home Secretary as to what trades or processes of trade have under Section 8 of the Factories Act, 1891, been certified by him as dangerous or injurious to health or dangerous to life and limb.—In his reply Mr. Asquith mentioned the following—viz., the manufacture of white, red, orange, and yellow lead, smelting and enamelling works, the manufacture of colours, lucifer matches, and earthenware, certain processes in the manufacture of explosives, chemical works, electric accumulator works, flax mills, linen factories, brass mixing and casting, and quarries. The clause in the new Bill empowering the Secretary of State to prohibit the employment of women or children or young persons is directed, said Mr. Asquith, to the case of trades where, from the nature of the industry itself, whatever precautions may be taken to ensure the safety of those concerned, particular processes cannot be carried on by particular classes of workers for reasons of age or sex without running exceptional risks to life or health.

FRIDAY, MARCH 8TH.

London University.

In Committee of Supply a small supplementary vote was asked for London University, and Sir Albert Rollit took advantage of the opportunity to press the Government for an increase in the annual grant to the University. The hon. member called special attention to the need for new laboratories.—The Chancellor of the Exchequer, while admitting the reasonableness of the demand, said that the state of the public funds did not enable him to meet it.—Sir Julian Goldsmid, who is a member of the Senate of the University, said that the fees for the students who were examined exceeded in amount the cost of the examinations, so the Treasury actually made profit out of the transaction and ought to be prepared to increase the grant. Other members having pressed the matter, the Chancellor of the Exchequer spoke again and promised to assist the University on the earliest opportunity.

MONDAY, MARCH 11TH.

Rabies in Dogs.

Mr. Herbert Gardner, answering a question put by Major Rasch, said that the number of cases of rabies in dogs during the six years 1889, 1890, 1891, 1892, 1893, and 1894 had been 312, 129, 79, 38, 93, and 248 respectively. Practically the whole increase in 1894 as compared with 1893 had been in the two counties of the West Riding of Yorkshire and Lancashire, and the Board of Agriculture had constantly been in communication with the local authorities in those counties as to the measures to be taken to bring about a more satisfactory position as regards this dangerous disease.

The Medical Division of the War Office.

Mr. Hanbury asked the Financial Secretary to the War Office whether he was now in a position to state the result of the inquiries promised during the debate on the medical vote last year into the distribution of the duties of the medical division of the War Office.—Mr. Woodall replied that the Secretary of State had made full inquiry into the distribution of the work in this division and satisfied himself that the professional officers and the civilians were appropriately employed on professional and clerical work respectively. Medical officers who were necessarily changed frequently could not properly discharge the duties which devolved upon the principal civilian clerk.

TUESDAY, MARCH 12TH.

Deaths from Starvation.

In reply to a question, Mr. Asquith said that the return of deaths from starvation was at present in the hands of the printers, and would be issued as soon as possible. A considerable correspondence between the Local Government Board and boards of guardians respecting certain cases in the return was necessary before the matter could be got ready for the printers.

The Tuberculosis Commission.

Sir John Hibbert, answering a question put by Mr. Hayden, said that the total cost of this Commission might be put approximately at £7500. This amount included £4672 for special scientific investigations and an estimated expenditure of £2828 on printing. He understood that the proceedings of the Commission would not extend beyond the present financial year.

Drainage of London Barracks.

Lord Stanley inquired of the representative of the War Office when the drains of Chelsea Barracks, Wellington Barracks, St. George's Barracks, and Kensington Palace Barracks were last inspected, and Mr. Woodall replied that apart from the ordinary quarterly barrack inspections, when defects are reported and remedied, no special report on the drains of these barracks had been necessary, as nothing had occurred to arouse suspicion as to their sanitary condition.

BOOKS ETC. RECEIVED.

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

TO ADVERTISERS.

THE pressure on our advertisement space this week has necessitated the omission of some few of our clients' announcements.

CLERGYMEN AND CURES FOR INFLUENZA.

WE should have thought that clergymen had their hands full at the present time with the cure of souls. But this does not seem to be true of the Rev. J. E. Woodrow, of the Vicarage, Ormskirk, who advertises "A Sure and Certain Cure for Influenza," consisting of a certain amount of pure phenol in a bottle of water; children to have half the dose. Mr. Woodrow would do well to consult his bishop as to this use of his spare time and knowledge. From the medical point of view we assure him that he incurs a considerable responsibility in advising such remedies or any other for a disease so serious in itself, and lowers his office and his influence by such interference with the functions of another profession.

An Engineer.—The temperatures used in the preparation of margarine are, we believe, at no stage sufficiently high to destroy germs.

"THE JOURNAL OF COMPARATIVE PATHOLOGY AND THERAPEUTICS."

To the Editors of THE LANCET.

SIRS,—Your correspondent, "F.R.S.," would probably be able to see this journal at the library of the Royal Veterinary College, Camden Town. It is a journal devoted to veterinary science, was first issued in 1888, and is edited by Professor McFadyean. The publishers are Messrs. W. and A. K. Johnston of Edinburgh.

I am, Sirs, yours faithfully,

March 9th, 1895.

J. W. C.

"* We have received numerous answers for "F.R.S.," and must apologise to the Editor of the *Journal of Comparative Pathology and Therapeutics* for not immediately recollecting the publishers of his valuable quarterly.—ED. L.

THE CASE OF MR. C. BRYAN TOWNSEND.

THE following additional subscriptions have been received or promised, and are hereby acknowledged with grateful thanks:—

Previously acknowledged £22 9 0	Mr. J. Terry (Bath) ...	25 0 0
Mr. H. S. Hughes (Lewes) 2 2 0	Dr. Joseph Kidd (Black- heath) ...	5 0 0
Mr. N. Davies-Colley ... 2 2 0	Dr. Wm. Vawdrey Lush (Weymouth) ...	2 2 0
Anonymous (Manchester) 0 10 0	Dr. Hugh Ealand (Puckeridge) ...	1 1 0
Mr. E. Walter Greene (Bury St. Edmunds) ... 2 2 0	Mr. Ed. B. Holwell (Leeds) ...	1 1 0
Dr. de Havilland Hall ... 0 10 0	Mr. J. T. Musgrave (London) ...	1 1 0
Dr. Hamilton (Burton-on- Trent) ... 1 1 0		
Mr. Chas. Terry (Bath) ... 5 0 0		

Further subscriptions are earnestly requested, and will be received and acknowledged by the Rev. H. Townsend, 41, King Henry's-road, London, N.W.

Mr. T. W. Morris.—The arrangement is not one that we can recommend or assist. If no actual covering is contemplated, our correspondent's scheme at any rate places the qualified assistant in an inferior place to the unqualified principal, and that in itself is wrong.

"A QUESTION OF DOOR-PLATES."

To the Editors of THE LANCET.

SIRS,—Your correspondent "H." seems very sensitive about reputable foreign degrees being registered; but he may be surprised to know that this has been the custom for some considerable time, and I think the General Medical Council may be left to see that the privilege is not abused. It is not necessary to cross the water to obtain a degree which is more precious from a monetary than any other point of view, so that it is as yet very unsafe ground to draw many comparisons. It is a strange weakness of our profession that the old subject of degrees and titles is ever to the front. I should think the Editors of THE LANCET are satiated of it. I can say that a large body of the readers are. Surely we are in an age when a man should be judged by what he can do rather than by what he is and for which he is generally credited? As to brass door-plates, I think usage is in the direction of their being smaller every year, judging by appearances, and a very good thing too. Why not let a man call himself anything he likes; it would not make him what he is not. Personally I would call all medical men "Doctors," letting those who select surgery as a speciality style themselves "Surgeons," and those who possess an M.D. use it, and no honourable man would be ashamed of the affix on suitable occasions, but we like a display of good taste as well as good tone.

I am, Sirs, yours truly,

March 2nd, 1895.

REGISTERED FOREIGN GRADUATE.

To the Editors of THE LANCET.

SIRS,—Will you permit me to reply to the letter of "H" in THE LANCET of March 2nd? Any man, medical or otherwise, is quite entitled to display the distinguishing initials of any degree or diploma he may possess, whether granted by a foreign or home corporation; when, however, it refers to medicine, and is not a registrable diploma, or only registrable as an "additional qualification," while it is neither illegal, dishonest, nor dishonourable to make what display he chooses of such diploma, it is at the same time somewhat despicable that a man should do so with the intention of obtaining undue honour or credit among his fellow men. I may point out that a man holding only an unregistrable degree may display what he likes upon his door if he does not practise. It is practising which herein constitutes the crime.

I am, Sirs, yours truly,

London, March 5th, 1895.

H. CRITCHLEY, M.A., M.D.

To the Editors of THE LANCET.

SIRS,—Your correspondent, "H.," writing on this matter, is needlessly distressed. "Would it surprise him" to learn that in the official Medical Register there are the names of many honourable men of unquestionable standing and position who hold the M.D. degree of foreign universities duly and legally registered? Also, that these gentlemen are fully recognised and addressed as "Doctor" by the Registrar in all official communications from him, as well as by their fellow practitioners, who are probably as zealous for the honour of the profession as your correspondent, though perhaps less cautious and censorious.

I am, Sirs, yours faithfully,

March 12th, 1895.

M.R.C.P. & M.D. (DULY REGISTERED).

MEDICAL ADVERTISING IN WEST HAM.

THE following card is being distributed in West Ham:—

"S. L. Popham, M.D., Surgeon, 55, Fairland-road. At Home—10 to 12 A.M.; 6 to 7 P.M."

We need not say that this distribution is not in accordance with the traditions of the profession.

Mr. R. S. Trotter.—The idea of treating cases of Addison's disease by the administration of an extract of the suprarenal body has been suggested from more than one quarter since the successful employment of thyroid extract in myxœdema. We are not certain that any records of cases so treated have been published as yet; but we have reason to believe that particulars of researches in this direction will shortly be made known in this country.

PROFESSIONAL SANCTIONS OF QUACKERY.

THE advertising columns of the *Sun* (March 8th, 1895) contain laudatory notices of "Norton's Curanillo," purporting to be signed respectively by J. Alfred Wanklyn, M.R.C.S. Lond., Professor of Chemistry, &c.; Charles W. De Lacy Evans, M.R.C.S., Ph.D., Solly Medallist of St. Thomas's Hospital, &c.; J. Brodie, L.R.C.P., L.R.C.S., &c. It is not easy to understand how medical men justify themselves in giving such notices to quack medicines. The evil is a great one, and calls for some notice at the hands of the medical corporations.

"SULPHUR v. ANTITOXIN IN THE TREATMENT OF DIPHTHERIA."

To the Editors of THE LANCET.

SIRS,—Mr. Lennox Browne has certainly formed a very different impression from what I intended to convey in the sentence he quotes from my letter. If two or more remedies have been proved to be useful in a certain case there can, of course, be no objection to a combination. When, however, we have a deadly enemy to fight, and it is uncertain how to prevent the raids of that enemy, I am of opinion that we are justified in simply using one form of attack only until we discover which form or combination of forms will annihilate the foe, and it is only by this means that posterity will benefit by the researches of the present day. If two or more remedies are used and the observer gives all the credit to one of these without due trial exactly what Mr. Lennox Browne fears will happen. Many lives will be sacrificed and no advance will have been made. I did not cast any imputation on the efficacy of antitoxin because Dr. Hamilton used sulphur simultaneously with it; but I certainly took exception to him giving the whole credit to antitoxin, and came to the conclusion that if he published his successful cases in which he used antitoxin he would have headed his article as "So many Cases treated successfully by Antitoxin." Mr. Lennox Browne will probably say I am not justified in coming to this conclusion, because he says in his letter that antitoxin was used as an auxiliary only in the results published in THE LANCET of Feb. 2nd, p. 305. I have read through the accounts published in that number, and I can find no allusion to other remedies being used in combination. On the contrary, the only mention of other methods of treatment is made by Dr. Caiger of the South-Western Fever Hospital, who says: "Results which my experience justifies me in asserting could not have been expected with previous methods of treatment." I should be glad to hear if Dr. Caiger and the other gentlemen whose names are connected with the various accounts have given either sulphite of magnesium or sulphur a fair trial. The results published by those using these two remedies compare more than favourably with the results obtained so far with antitoxin. Medical and lay papers have filled their columns with accounts of the "new cure for diphtheria." Sulphur I claim to be a surer cure. If it is of only equal value it is a far better remedy to use, for it is always at hand and is free from many objections that may be raised against antitoxin. One shudders to think of the terrible havoc that would be wrought if the tube contained not antitoxin, but the inert rubbish—if nothing worse—often contained in tubes sent supposed to be filled with vaccine lymph. I should like to know how we are to contrast the usefulness of different remedies other than by mathematical calculations. If Mr. Lennox Browne does not believe in mathematical calculations, why does he tell us that a mortality of 5 per cent. is an object lesson? 0 per cent. is a more striking object lesson. This has been the success of sulphur in some hands since using it in the treatment of diphtheria. I know many will say the diagnosis has been wrong, but why should a man's power of diagnosis be faulty after using a certain drug when it was not questioned before using it? Then one cannot forget cases where the diagnosis had been made by another man, and the man called in confirmed the diagnosis and recommended sulphur, bringing about results highly satisfactory to all concerned. I should, indeed, be sorry to see any human being treated other than with a sense of grave responsibility. If, however, permanent benefit is to be the result of any treatment it must be as far as possible scientific and not empirical.

I am, Sirs, yours faithfully,

Aberdovey, March 4th, 1895.

W. HAWKINS CUTHBERT.

"BOOKS ABOUT MEDICINE."

To the Editors of THE LANCET.

SIRS,—In answer to your correspondent "Enquirer," Dr. Doran appears to have gained his facts from B. F. Boerner's pamphlet "De Cosma and Damiana," published at Helmsstadt in 1751. It is a matter of common knowledge that the brethren preceded St. Luke in the estimation of our ancestors. They were the patrons of the barber-surgeons throughout Europe, as well as of the Medici family. In England they were made to act as supporters to the shield granted to the Fellowship of Surgeons in London in 1492, as may be seen in Mr. Sidney Young's valuable work on the Annals of the Barber-Surgeons. They are not present in the original grant of arms, but have been introduced at a later period without heraldic authority. A detailed account of the saints will be found in Mrs. Jameson's "Sacred and Legendary Art," vol. II., pp. 433-439, ed. 1890.

I am, Sirs, yours faithfully,

March 8th, 1895.

D'ARCY POWER.

* The worship of these saints was well established in Italy from a very early date, and the rites, prominently those of Phallicism, will not bear much detailed description.—ED. L.

"DR. GOFF, 179, WESTMINSTER BRIDGE-ROAD, LONDON, S.E."

SUCH is the address at the foot of one of the worst specimens of a medical handbill which we have seen. Its chief object is to laud the virtues of "Dr. Goff's reliable Female Pills for all ages," and "Reliable Female Mixture for obstinate cases of Irregularities." They are recommended for all females, married and unmarried, to be taken before menstruation. The handbill admits of very bad construction, and in any view is discreditable to a registered medical man. But is Mr. Goff such? In the Medical Register for 1892 we find that a Mr. George Romaine Goff, L.F.P.S. Glasg., L.S.A. Lond., resided at 179, Westminster Bridge-road, Lambeth; but we can find no mention of this gentleman again either in the official roll or in the Medical Directory. If this is the "Dr." Goff of the evil handbills the bodies from whom he has received his diplomas should proceed immediately to point out to him the reprehensibility of his methods. But if "Dr." Goff is not Mr. George Romaine Goff he would not appear to hold any medical degrees, or to be more amenable to the discipline of corporations and of the General Medical Council than other quacks.

W. G. G.—Income Tax Commissioners who are quite independent of the Revenue Department are appointed for the purpose of protecting the taxpayer, and our correspondent should, we think, apply to them. A brochure entitled "Income Tax and How to Get it Refunded" is published by Messrs. Effingham Wilson and Co. of the Royal Exchange and sold for a shilling, and a society which interests itself in these matters, named the Rate and Taxpayers' Assessment Protection Association, Ltd., has offices at 10, Serjeant's-inn, Fleet-street.

"THE INFLUENZA EPIDEMIC."

To the Editors of THE LANCET.

SIRS,—Mr. Terry asks if anyone has seen marked throat affection in cases of influenza. In every case I have seen there has been a decided sore-throat. The pharynx has assumed a strong redness, very similar to what is present in scarlet fever, but without any sign of ulceration. There is no pain in swallowing, but the patient complains of the throat being parched and hot. In one case there was acute eczema on one side, the corresponding tonsil being large, puffy, and encroaching on the isthmus. The thirst in every case has been most urgent and intense. Bronchitis of a more or less acute character has shown itself on the third or fourth day. The attack has been ushered in by distinct shivering, weariness, and severe headache, but no coryza. I have no doubt the essential infectiveness of this disease is mainly due to the condition of the peculiar local faucial lesion, which is unlike in appearance that of any other disease I know. I have found swabbing the inflamed area with borate of glycerine several times a day of great benefit. It cools and to some extent allays thirst and the dry and hot scalding sensation so much complained of. We hear a great deal of "chills being taken." This is an error in the majority of cases. The shivering is one of the first symptoms indicative of the assault or invasion of the disease, and has no connexion with a supposed "chill."

I am, Sirs, yours faithfully,

Southport, March 11th, 1895.

G. B. BARRON, M.D., &c.

THE AMENITIES OF THE PROFESSION.

T. R.—The rule still holds that the widow of a medical man is entitled to much consideration and, if need be, to gratuitous medical attendance from the profession. The rule is not an absolute one. It is subject to considerations of reason and circumstance, and should not be pressed too rigidly on either side; but, subject to these qualifications, it is one to be respected.

ERRATUM.—On p. 583 of our issue of March 2nd, under the heading "Royal College of Surgeons in Ireland," a comma should be inserted between the surname "Penrose" and the place-name "Burton."

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*Scotsman*, *Southport Guardian*, *Bridge of Allan Reporter*, *Dundee Advertiser*, *Horncastle News*, *Carlisle Express*, *Cincinnati Tribune*, *Flintshire Observer*, *North Star*, *Swansea Journal*, *Walsall Advertiser*, *Sussex Daily News*, *Spalding Free Press*, *Dover Telegraph*, *Leicester Post*, *Birmingham Gazette*, *Newcastle Leader*, *Warwick Times*, *Leek Times*, *New York Tribune*, *Stafford Advertiser*, *Manchester Courier*, *Sheffield Telegraph*, *Glasgow Evening News*, *Cornish Telegraph*, *Leeds Mercury*, *West Middlesex Standard*, *Hertfordshire Mercury*, *Public Health Local Government Chronicle*, *Mining Journal*, *City Press*, *Pioneer Mail*, *Bristol Mercury*, *Architect*, *Liverpool Daily Post*, *Vegetarian Builder*, *Times of India*, *Yorkshire Post*, *Weekly Free Press* and *Aberdeen Herald*, *Reading Mercury*, *Sanitary Record*, *Orkney Herald*, *Dumfries Standard*, *Surrey Advertiser*, *Guy's Hospital Gazette*, *East Grinstead Observer*, *West Middlesex Advertiser*, *Durham County Advertiser*, *Cheltenham Examiner*, *Oswestry Advertiser*, *Waterford Chronicle*, *Leighton Buzzard Observer*, *Durham County Advertiser*, *Umpire*, *Mayo Examiner*, *Army and Navy Gazette*, *Macclesfield Courier*, *Westmeath Examiner*, *Liverpool Express*, *East London Observer*, *Craven Herald*, *Roscommon Messenger*, *Hampshire Chronicle*, *Zoophilot*, *Indicator Cork Daily Herald*, *Wrexham Advertiser*, *Fulham News*, &c., &c.

ABSTRACT OF
The Goulstonian Lectures
ON
THE SUPRA-RENAL BODIES.

*Delivered before the Royal College of Physicians of London
on March 19th, 21st, and 26th, 1895.*

By **H. D. ROLLESTON, M.A., M.D.CANTAB.,
F.R.C.P. LOND.,**

FELLOW OF ST. JOHN'S COLLEGE, CAMBRIDGE; ASSISTANT PHYSICIAN
AND LECTURER ON PATHOLOGY AT ST. GEORGE'S HOSPITAL.

LECTURE I.

Delivered on March 19th.

**ANATOMY, HISTOLOGY, AND MORBID ANATOMY OF
THE SUPRA-RENAL CAPSULES.**

AFTER thanking the College for the honour conferred upon him the lecturer described the most satisfactory method of exposing and removing the supra-renal capsules from the body after death, and laid stress on taking them out before, not with, the kidneys. The exact anatomical position and relations of the organs were then described. These organs lay not on the top of the kidneys, but at their upper and inner borders, reaching down to the hilum of the kidney. The right supra-renal body lay under the inferior vena cava along its inner border, and was for a varying extent in direct contact with the hepatic flexure of the duodenum. The oblique undulation in the right supra-renal body was described and compared with its vertical direction on the left side. The difference in the conformation of the two bodies was explained as being a result of the different pressures to which they respectively were exposed. The kidneys and supra-renal bodies were of the same size at the third month of intra-uterine life; at the sixth month the kidneys were twice and at birth three times the size of the adrenals. In adult life the relation was 44 to 1. There was no evidence to show that the supra-renal bodies in negroes were larger than in white men. Abnormal processes in connexion with the supra-renal body were mentioned. The absence or atrophy of these organs in hemicephaly and anencephaly was referred to. Accessory supra-renal bodies were commonly found, if looked for in the connective tissue around the main organ; they also occurred in the solar plexus, along the spermatic vessels, and in the broad ligament of the uterus. Structurally the smaller accessory supra-renal bodies were composed of the cortical substance, the larger of cortex and medulla. Accessory supra-renal bodies embedded in the kidney, and more rarely in the liver, were called "rests." In the kidney these "rests" appeared (1) as multiple round nodules which might be so fatty as to be called renal lipomata; (2) as single expanded plaques met with on the surface of the upper part of the kidney, where the pressure of the liver or spleen produced flattening.

HISTOLOGY OF THE SUPRA-RENAL BODIES.

A brief account of the three zones of the cortex was given. The zona reticularis of the cortex could not be sharply marked off from the medulla; its cells stained brown with chromic acid and contained a varying amount of pigment. Canalis had observed mitosis in the cortex, but never in the medulla. Dr. Hill of Cambridge had kindly informed the lecturer that from the active mitosis he had observed in the zona reticularis it was probable that cell multiplication occurred here in adult life. Fatty change in the cortex was normal in adult life and was always much more marked than in the medulla. The cells of the medulla stained brown with chromic salts, but this reaction gradually diminished, until twelve hours after death it had disappeared. Stilling had called these cells "chromophile," and had met with similar ones in the sympathetic and intercarotid gland of animals. Manasse had described a hyaline material in the veins of the medulla which was derived from the adjacent cells. Auld had described the medulla as a tubulo-alveolar gland with colloid material in its acini. The presence of ganglion cells in the medulla was discussed, and the conclusion was that there probably were some present. The relation of the cortex and medulla was next considered. The current view was that they were

No. 3734

developmentally, structurally, and functionally distinct. The medulla embryologically was connected with the sympathetic and the cortex with the mesoblast or Wolffian body. Creighton's observations on the homologies of the supra-renal bodies, however, pointed to the cortex and medulla forming a functional whole, and this view the lecturer was inclined to adopt on histological grounds. Quite recently, however, Schäfer and Oliver¹ had shown that the medulla alone contained the active principle of supra-renal extract.

VARIOUS MORBID CONDITIONS OF THE SUPRA-RENAL BODIES.

The lecturer said that, though a sketch of the physiology would naturally come next, it was more convenient to refer to the chief lesions of morbid anatomy attacking them before considering the function of the supra-renal bodies, since that subject was so closely connected with the explanation of Addison's disease. Some degree of atrophy was normal in old age, but apart from this atrophy occurred occasionally earlier in life, and when extreme it was sometimes the cause of Addison's disease. The lecturer in an examination of 1050 bodies had noticed atrophy under the age of forty-five years on six occasions; in none of them was the atrophy so extreme—viz., to the size of peas—as had been described in some cases of Addison's disease; in none of these cases were the symptoms of Addison's disease present. Hæmorrhage into the supra-renal bodies was occasionally spontaneous, but was more frequently traumatic. Dr. Spenser had shown visceral hæmorrhages at birth to be far from uncommon. In 130 stillborn children he had found hæmorrhages into the medulla of the supra-renal in 24; half of them were bilateral. These hæmorrhages were more common in difficult labours. The after-result of such hæmorrhages might possibly lead to atrophy of the organ. After referring to cloudy swelling, the lecturer quoted Dr. Atlee's recent, as yet unpublished, work on Fatty Changes in the Supra-renal Bodies of Children. In wasting children the supra-renal bodies were extensively occupied by fat; they were more constantly affected than the liver. In stillborn children the amount of fat was very moderate; in infants dying from diseases other than marasmus the fatty change was never so marked as in marasmus. Experimentally Atlee found that starvation, suppuration, and poisoning led to marked steatosis. The question whether the change was of the nature of a degeneration or of an infiltration was discussed. The lardaceous change attacked the vessels on the cortex of the organ. The medulla might be affected to a lesser degree. In 15 cases of marked lardaceous disease the supra-renal bodies were affected eight times. Cysts might be due to hæmorrhages, to ecchinococci, or possibly to softening of adenomata, but were rare. Tubercle occurred comparatively often in the supra-renal bodies. In 1050 necropsies death was found to be due to tubercle in some form or other in 131 cases, and in 18 of these caseous material was found in the supra-renal bodies. There seemed to be an immunity on the part of the supra-renal bodies from tubercle during the first years of life.

	Years.								Total.

Chronic tuberculosis always began in the medulla.

SIMPLE TUMOURS.

Adenomata were of two kinds: (1) small multiple yellowish nodules on the cortex composed of the cells of that region, showing marked fatty change; (2) large single tumours arising from the cortex, magnified editions of the former. They had been called hyperplastic tumours, struma lipomatosa supra-renal, or supra-renal goitre. On the analogy of exophthalmic goitre symptoms might have been expected to be connected with these supra-renal adenomata. The extreme fatty change showed that they were probably inactive, and this, together with the apparent functional

¹ Proceedings of the Physiological Society, March 18th, 1895.

inactivity of the cortex from which they arose, accounted for the absence of any symptoms. Exceptional tumours, such as angioma and ganglionated neuroma, had been recorded as occurring in these organs.

MALIGNANT TUMOURS.

Both sarcomata and carcinomata occurred primarily; the former were the commoner, and showed a marked tendency to the formation of hæmorrhagic cysts and of necrosed areas. Supra-renal "rests" in the kidney might take on malignant growth, and thus give rise to a renal sarcoma. In the same way some primary sarcomata of the liver might be explained. Secondary carcinomata and sarcomata were occasionally found. Out of sixty-three cases of carcinoma of various parts of the body, the lecturer had found secondary growths in the supra-renal bodies in seven cases. Dr. Norman Moore had recorded three secondary growths in 102 cases of carcinoma. In twenty-four cases of sarcoma secondary growths were noted by the lecturer twice. Dr. N. Moore's figures were twenty-one cases of sarcoma with five secondary growths, of which two were described as endothelioma secondary to primary growths in the heart.

LECTURE II.

Delivered on March 21st.

PHYSIOLOGY OF THE SUPRA-RENAL BODIES.—MORBID ANATOMY OF ADDISON'S DISEASE.

The earliest researches were those of Brown-Séquard. By removing the adrenal bodies and observation of the results he came to the following conclusions: (1) that these organs are essential to life; (2) that they modified or destroyed a substance which otherwise transformed itself into pigment; (3) that when the organs were destroyed or removed this substance collected in the blood; (4) that removal was rapidly fatal, and that injection of the blood of an animal thus killed into a healthy animal led to symptoms like those of removal. Gratiolet, Phillippeaux, and G. Harley repeated these experiments and came to the conclusion that the supra-renal bodies had no special function, and that the fatal results were due to peritonitis, hepatitis, or damage to the sympathetic. Brown-Séquard in a further paper repeated his conclusions and denied that the results of removal were due to concomitant lesions. The negative results obtained by ablation might have been due to a compensatory activity of accessory supra-renal bodies, which Stilling had shown underwent hypertrophy after removal of the main glands. Tizzoni's observations were next described at length. Removal of one or of both supra-renal bodies gave rise to death with inflammatory changes in the central nervous system. Death might be postponed for years or might occur shortly after the operation. Since the same result followed the removal of one or of both organs, Tizzoni considered that the effects were not due to a toxin, but to disturbance of the circulation in the nervous system set up by irritation of the sympathetic connected with removal of the supra-renal body. These changes were not constant and so far had not been confirmed. Stilling thought the changes were set up by extension of inflammation from the wound. Tizzoni regarded the supra-renal bodies as only of importance from their close relation to the sympathetic. McMunn believed that the supra-renal bodies picked out effete blood pigment and its accompanying proteids from the blood, and that when these organs were destroyed or removed, pigment and poisonous bodies accumulated in the blood. Neurine had been thought to be the poisonous body which, when not removed, accumulated and gave rise to the symptoms of Addison's disease; this did not appear to be the case. There was no proof that leucin, leucithin, taurocholic acid, &c. were removed by the supra-renal bodies, or that accumulation of them gave rise to symptoms analogous to those of Addison's disease. Removal of the supra-renal bodies had been shown (Langlois and Abelous) to produce a fatal toxæmia, which could be prevented by the injection of supra-renal extract. Injection of the blood of acapsulated animals into healthy ones gave rise to symptoms like those following removal. The toxic body or bodies had an effect analogous to that of curare; they were probably due to muscular metabolism and had a resemblance to the poisonous bodies found in the blood of tetanised animals. Animals from whom the supra-renal bodies had been removed showed rapid and persistent fatigue which had been compared to the asthenia of Addison's disease. These writers regarded the supra-renal capsules as active glands, producing an internal secretion, which antagonised

toxic substances formed in the metabolism of the body. Ligature of the pedicle, including the vein, of the supra-renal bodies had been shown to be more fatal than ablation (Boinet). Ligature abolished the functional activity of the glands and gave rise to less damage to the adjacent sympathetic. If one supra-renal body was removed the other had been noticed to hypertrophy; if the remaining one was separated from its nervous connexions and left *in situ* no bad results followed; if, however, the hypertrophied organ was removed death resulted (Thirolloix). Therefore, removal gave rise to symptoms from interference with the functions of the glands, not from concomitant isolation of the sympathetic. Schäfer and G. Oliver¹ had injected supra-renal extract into animals. They had found: 1. A rise of blood pressure due to arterial constriction, best seen after section of the vagi, by which means the concomitant inhibitor of the heart was prevented. The constriction was due to peripheral action, since it persisted after section of the spinal cord and nerves. This high blood pressure was not affected by stimulation of the depressor. The rise in blood pressure was transient. 2. Cardiac inhibition due to vagus stimulation; stimulation of the cardiac muscle, leading after section of the vagi to acceleration and augmentation. 3. Paralysis of voluntary muscles due to modification of muscular contraction akin to that produced by veratria, but not in any way analogous to the action of curare. Since this effect lasted longer than the cardio-vascular phenomena, the extract probably became stored up for some time in the muscles. 4. That the active principle of the extract is only present in the medulla, and not at all in the cortex. B. Moore² had found that the active principle was not a proteid or a carbohydrate, that it was not affected by acids or by boiling for some minutes, but that it was destroyed by alkalies and by continued boiling. It dialysed and had a powerful reducing action. Its properties resembled those of a reducing agent described by Vulpian in 1856 as special to the medulla of the supra-renal bodies. The active principle had not been isolated.

Three deductions were possible from these researches: (1) that the supra-renal bodies had no proper function and were only important from their close relation to the sympathetic; (2) that these organs were *excretory* glands, removing pigment and toxins from the circulation; (3) that they were *secretory* glands, providing an internal secretion which was of use in the economy. The evidence was sufficiently strong to show that the supra-renal bodies had some definite function. The lecturer said it was more convenient to postpone the discussion whether the function was excretory or secretory until the explanation of Addison's disease was dealt with, since the physiology and pathology of these bodies were so inextricably blended.

MORBID ANATOMY OF ADDISON'S DISEASE.

Addison originally described eleven cases, of which six were tuberculous, one of cirrhotic atrophy, in three cases malignant growths occupied the supra-renal bodies, and in one a nodule of carcinoma blocked up the supra-renal vein. Addison's views were quoted. The view of the unity of Addison's disease (Wilke) was that all genuine cases of Addison's disease were due to one and the same lesion of the supra-renal bodies: a chronic inflammation comparable to hepatic cirrhosis. Though Addison's disease was most commonly due to tuberculous disease of the adrenal bodies, well-authenticated cases due to simple and cirrhotic atrophy had been recorded. The association of Addison's disease and malignant growths in the supra-renal capsules was then referred to. The sympathetic in the neighbourhood of the adrenals was sometimes sclerosed, sometimes normal. Von Kahlden had described certain changes in the semilunar ganglia as of great importance in the causation of Addison's disease; these, however, resembled those normally found in adults by Hale White. Cases had been recorded where the supra-renal bodies themselves were healthy, but where the sympathetic was involved in a mass of growth. The distribution of cutaneous pigment in Addison's disease was described as an exaggeration of that normally met with. The pigment melanin was present in the stratum Malpighii of the epidermis and in "carrier cells" in the dermis. The carrier cells probably conveyed pigment from the blood-vessels to the epidermis; in Addison's disease this transference was exaggerated owing to functional changes in the vessels. Professor Delépine had suggested that melanin was

¹ Proc. Phys. Soc., March, 1894-95.
² *Ibid.*

normally the antecedent, not the derivative, of hæmoglobin. Auerbeck and Burger's view that the pigmentation of Addison's disease was due to very active metabolism of the cells of the stratum mucosum was mentioned. Pigmentation of mucous membranes was rarer, and was usually regarded as a more reliable sign of Addison's disease than cutaneous bronzing. Dixon Mann described the pigment as situated in the keratin, and not in the epithelial cells of mucous membrane, and pointed out that its occurrence depended on irritation. Pigmentation of serous membranes was probably due to past inflammation; its presence had been recorded almost exclusively in the peritoneum.

OTHER ANATOMICAL LESIONS MET WITH IN ADDISON'S DISEASE.

The lymphoid follicles of the stomach and intestine were often enlarged; the spleen was not infrequently enlarged and softened, and the thymus gland had been found to be persistent. This evidence of activity in lymphoid tissue was compatible with the view that in Addison's disease toxic bodies were present in the blood, since in animals leucocytosis followed the injection of bacterial poisons, and leucocytosis presumably meant increased activity of the lymphoid tissue of the body. Tizzoni had quoted two cases of Addison's disease in which lesions of the central nervous system, somewhat like those which he had obtained experimentally, had been described.

Three Lectures

ON

TRAUMATIC INFECTION.

Delivered at the Royal College of Surgeons of England on Feb. 25th and 27th, and March 1st, 1895.

By C. B. LOCKWOOD, F.R.C.S. ENG.,

PROFESSOR IN SURGERY AND PATHOLOGY, ROYAL COLLEGE OF SURGEONS;
ASSISTANT SURGEON TO ST. BARTHOLOMEW'S HOSPITAL; SURGEON
TO THE GREAT NORTHERN CENTRAL HOSPITAL.

LECTURE III.

Delivered March 1st.

VARIOUS INFECTIVE CONDITIONS.

Streptococcus Pyæmia: Bacterial Emboli in Organs apparently Normal.—Streptococæmia.—Urine in Streptococæmia.—Mixed Infections.—Angina Ludovici with Bacillary Septicæmia.—Conveyance of Infection by Contiguity; Septic Pneumonia.—The Local Infection in Angina Ludovici.—Consecutive Infection: The Pathology of Hæctic Fever.

GENTLEMEN,—In this third lecture I propose to describe cases of traumatic infection which do not clearly fall under the preceding headings. But first I will describe a case of pyæmia which presented some instructive features, especially that the naked-eye appearances of infected organs cannot in the least be trusted to indicate the absence of infection.

STREPTOCOCCUS PYÆMIA: BACTERIAL EMBOLI IN ORGANS APPARENTLY NORMAL.

Pyæmia is one of the best examples of septicæmia with subsequent sarcopæsis. I only propose to mention one example of pyæmia which was of the streptococcus variety, because it shows how easily the infective diseases may be overlooked if reliance be given to naked-eye evidence, and that bacterial emboli may be found in organs otherwise normal.

CASE 14 (Figs. 20 and 21).—An infant a year and ten months old was burned upon the arm. The burn was of the second and third degree, and not extensive. It suppurated, and the infant became ill, with a temperature of 102° F. An abscess formed in the subcutaneous tissue of the chest and a rash overspread the body. After the appearance of this rash the infant was isolated, scarlet fever being suspected. Death ensued without any complications such as nephritis, meningitis, or pneumonia. At the examination the burn, which involved about half the arm, looked quite healthy. The parotid region was swollen, but did not contain pus. The lymphatic glands beneath the angle of the jaw were filled with softening caseous material. There was a subcutaneous abscess as big as the palm of the hand

upon the side of the chest, and filled with thick pus. All the abdominal and thoracic viscera were individually examined and pronounced to be normal, as were also the serous and mucous coats of the intestines. The examination was made by my colleague, Mr. James Berry, whose name is a guarantee for the thoroughness and correctness of it. He concludes his report by saying that "the death was apparently due to the suppuration of the neck and

FIG. 20.

Streptococcus pyæmia. Streptococci in the walls of a subcutaneous abscess. (The lecturer is indebted to Messrs. Cassell and Co. for this figure, which is from his forthcoming article on Pyæmia in "A System of Surgery," edited by Mr. Treves, and now in the press.)

chest; perhaps to some meningeal trouble, as the head was not allowed to be examined." I cannot tell whether this surmise is correct, but the histological examination of some parts of the body gave the following results. The abscess wall was composed of fibrino-purulent material mixed with incredible quantities of streptococci in chains, both long and short, especially the last. (Fig. 20.) To the naked eye the kidneys and liver looked, as Mr. Berry said, quite normal,

FIG. 21.

Streptococcus pyæmia. Micrococci in the capillaries of a portal canal. In this case the liver and other organs were considered normal to the eye.

but the parenchyma of each was beginning to exhibit the early stages of cloudy swelling. Also in the liver a great many of the small vessels and capillaries of the portal canals, and also the vasa vasorum of the portal veins and of the bile-ducts, were plugged with micrococci. (Fig. 21.) These cocci were so crowded together that chains could not be recognised, but this is not

uncommon in streptococcus poisoning. Some blood which had remained in the hepatic veins contained occasional diplococci and short chains of cocci. In the cortex of the kidneys similar plugs of micrococci were found in the capillaries of the glomeruli and tubules, and especially in the vasa vasorum of the renal vessels; but these emboli were much harder to find in the kidneys than in the liver, being less numerous. As regards the cocci in the liver, it seems very evident that they had been carried there by the hepatic artery. It is probable that after a while they would have emigrated from the capillaries into the bile-ducts; indeed, the process seemed in places to have begun. Here we have an explanation of the presence of bacteria in bile without a macroscopic focus, such as an abscess, having been discovered. Hitherto bacteria found under such circumstances have been supposed to have been excreted with the bile. Had these plugs gone on to the formation of abscesses it is clear that the result would be very different from that produced by infection carried along the portal veins, but I am not aware that such differences have been described. It is interesting to note that although the kidneys contained capillaries plugged with micrococci yet albuminuria had not occurred, although it was frequently sought for. Lastly, the presence of the cocci in the vasa vasorum seems to me a fact of some moment. They had not begun to produce changes in the vessel walls, and it would be most interesting to speculate as to the ultimate result had the child survived. This case belongs to a class the seriousness of which is not always properly appreciated. Infants are most susceptible to both local and general infection, but the latter is often overlooked. I have no doubt whatever but that more searching and systematic examination of the tissues by more exact methods will vastly increase the rôle played by septicæmia in surgery.¹ The mortality after burns is a reproach to surgery. It could often be avoided by the skilful use of antiseptics.

CASE 15.—To control the investigation of this case of streptococcus pyæmia, that of a child who died with an extensive burn of the chest and abdomen may be mentioned. When the histological investigation of the lungs, liver, spleen, and kidneys was made by Dr. Blackwell and myself we were ignorant of the clinical details or of the result of the post-mortem examination, which was performed by Mr. Berry twenty-eight hours after death. We could find no bacteria in any of the tissues or organs, and came to the conclusion that death had been due to acute bronchitis. We afterwards learnt that this was correct, and that the burns were supposed to have been caused by the application of poultices intended for the relief of the bronchitis.

The foregoing case of streptococcus pyæmia might have been mistaken for one of scarlet fever in which streptococcus poisoning had occurred had it not been for the abscess upon the chest wall. Cornil and Babes² give a figure of the kidney after scarlet fever with a streptococcus embolus in one of the capillaries. Their specimen was apparently the same as that which I have described, except that there was also amyloid disease. The same authors give other figures of streptococci in the renal vessels in scarlet fever.³ They seem a common complication. Cultures showed that they were the streptococcus pyogenes. Leber and Wagenmann have described a case of streptococcus poisoning in an infant, but seem to have given their attention to the local lesions and not to have examined some of the organs because they looked normal. However, streptococci were found by them in the skin, eye, orbit, kidneys, and supra-renals.

STREPTOCOCCÆMIA.

Streptococciæmia is, I believe, not rare in infants and young children. As a rule, they recover from it after having sustained severe damage to one or other of their organs. Lately I had under my care in St. Bartholomew's Hospital a case exceedingly like the one which has just been narrated.

CASE 16.—The patient was a delicate female child aged two and a half years. She was admitted with an ulcer about an inch long and half an inch wide at the left margin of the anus. It involved the cutaneous and a little of the

mucous surface. At first it spread, but afterwards healed with simple local remedies. When admitted the child also had a loud systolic murmur, which still exists. Her liver, too, was enlarged almost to the umbilicus. Her legs were cedematous, with albumen in the urine. The temperature was usually subnormal, the thermometer as a rule registering 98° F. The coexistence of a point of inoculation, an endocardial bruit, acute nephritis, and swollen liver seemed to me to point so clearly to bacterial invasion that Mr. Farnivall, at my request, examined the blood and the urine. Nothing could be seen in the blood, nor could anything be grown from it upon the usual media. Fresh specimens of the urine collected with proper precautions contained cocci in short chains. I attached no importance to the absence of temperature in this case. As a sign of bacterial invasion the temperature is unreliable. It is quite usual to see no elevation of temperature even in such profound invasions as diffuse septic peritonitis. It is unreasonable to think that all bacterial poisons must be pyrogenous. The temperature, however, rose to 103° during the seventh week of her stay in hospital. A skin eruption, which was supposed to be measles, appeared at the same time. At this stage no streptococci could be found in the urine. The cause of the ulcer was never found out. Although a year has passed it has not been followed by any signs of syphilis. This is interesting because the mother had a syphilitic ulcer upon her face, but in the gummosis stage, and not, therefore, capable of infecting another with syphilis. That the ulcer of the mother was infected with other bacteria is certain. In a similar case I found staphylococci, streptococci, and bacilli.

Streptococci are easy to see in fluids, and appear in the urine soon after infection. The following is a common example of this.

CASE 17 (Fig. 22).—A healthy youth aged fifteen years crushed his hand and arm in a printing machine on Nov. 12th, 1892. Amputation was performed through the arm, and on the 13th his temperature was 101° F.; on the 14th it was 102°, and the urine contained a cloud of albumen. On the 24th he had pronounced pyæmia, with pus containing streptococci in the right hip, knee, and ankle. At the same time his urine contained numerous streptococci. (Fig. 22.) No examination

FIG. 22.

Streptococcus pyæmia. Streptococci in pyæmic urine. From a microphotograph by Mr. Cosens. (I am indebted to Messrs. Cassell and Co. for this figure. It is from a forthcoming article on Pyæmia by the lecturer in "A System of Surgery," edited by Mr. Treves, and now in the press.)

was permitted in this case, but in another of acute suppurative periostitis of the tibia following an injury the urine contained a similar cloud of albumen, and after death the kidneys were found acutely inflamed and studded with small abscesses and infarcts. The pus of the abscesses contained staphylococci similar to some found in the pus from the necrosed tibia.

I do not propose to discuss the conditions under which bacteria escape by the kidneys. This interesting question has been ably treated by Dr. Sherrington in his recent article and by others. Dr. Sherrington's work⁴ leads him to the conclusion

¹ Dr. A. S. Blackwell and myself were quite unable to demonstrate the conditions in the liver and kidneys by Gram's method. We succeeded by long immersion in the eosin and methyl blue solutions, from four to six days being requisite. I am much indebted to Dr. Blackwell for his trouble.

⁵ The Escape of Bacteria with the Secretions. Journal of Pathology, vol. I., p. 276. This valuable paper gives a full bibliography.

that "the evidence is against believing that when this transit of bacteria across the secreting membrane occurs the membrane is still normal in condition, although at the same time it need not be ruptured or pervious to red corpuscles." In the main Dr. Sherrington's observations confirm those of Klebs, Ogston, Fodor, Wyssokowitch, and many others.

CASE 18.—I thought at one time that I had obtained clinical evidence that the healthy kidneys excrete bacteria. I performed laparotomy for a pistol-bullet wound of the stomach. The wound was inaccessible, and other injuries combined to cause a fatal ending. After the operation a drain was placed in the peritoneal sac. Some blood-stained fluid drawn from this tube ten hours after the operation and sixty-four hours after the injury was full of cocci, streptococci, and short bacilli. Urine collected at the same time contained similar morphological varieties. The kidneys were histologically normal, with the exception of a slight interstitial nephritis which, I afterwards learnt, was of old standing. This case illustrates the difficulty of obtaining clinical evidence of the elimination of bacteria by healthy kidneys. Also, assuming the correctness of my observations, it shows that it may be wrong to consider, as I have done, that diffuse septic peritonitis is a purely local infection.

MIXED INFECTIONS.

I propose now to proceed with some complicated conditions of infection. In some of these the local disease was associated with a variety of bacteria, of which it seems possible that at least two species had invaded the body. In others it is probable that the original local disease was a pure infection which was supplanted by another of a severer type capable too of invading the body.

ANGINA LUDOVICI WITH BACILLARY SEPTICÆMIA.

CASE 19 (Figs. 23 and 24).⁹—In this case a bacillary septicæmia, closely resembling the cases I described in Lecture II. (Case 9),⁷ was unexpectedly met with in that grave disease described by Ludwig and called after him "cynanche or angina Ludovici." In narrating this case I propose, after giving the clinical history and morbid anatomy, to describe the septicæmia, and then discuss the cellulitis of the neck and its other complications. It will then be seen that the angina Ludovici is probably a mixed infection of the most complicated kind. Indeed, the examination of this and other cases leads me to think that several pathological conditions are included in the term "angina Ludovici." The case is also an example of the difficulty of the problems which confront inquirers into the infective processes of man. The patient was a man aged twenty-eight years. He was a heavy drinker. The cellulitis of the neck began without apparent cause and spread rapidly. On the fifth day the usual incisions were made and a little pus escaped. The patient became violent and was thought to be suffering from delirium tremens. On the sixth day oedema of the glottis caused so much dyspnoea that tracheotomy was performed. He became apathetic, drowsy, and unconscious, and died early on the eighth day. The actual cause of death was supposed to have been pneumonia. His highest temperature was 103° F., recorded on the seventh day. His urine contained a trace of albumen. Throughout his illness a purulent discharge ran from the floor of the mouth, and there was the usual horrible fetor. The drowsiness, apathy, and unconsciousness which supervened in this case remind me very strongly of the clinical condition of the woman who died from septicæmia after amputation of the breast for ulcerated scirrhus (*vide* Case 9, Fig. 10),⁸ and soon it will be shown that the same kind of bacillary infection existed in both cases. The delirium also may have been due to the septicæmia, and not, as was supposed, to alcohol. After death I found amongst the swollen and septic tissues of the neck engorged lymphatic glands and a clot in the left internal jugular vein. Both lungs were pneumonic and the kidneys swollen and engorged. The floor of the mouth was sloughing and ulcerated, and infiltrated with fetid pus. The heart and great vessels were normal, but gas escaped as I divided the pulmonary veins. The peritoneal cavity also contained some gas and blood-stained fluid. The spleen was enlarged and friable. The histological evidence of the septicæmia was in the kidneys. These organs were, as I have said, engorged with blood, some of which had remained in the veins and capillaries, forming a natural injection. Here and there this blood contained

a large bacillus which will be described presently. But in addition the vasa vasorum of some of the larger vessels of the medulla were packed with bacteria (*vide* Fig. 23), which I judged to be small, short bacilli. The appearances of these were the same as those of the cases of septicæmia which have been already described, and closely resembled the appearances seen in septicæmia artificially induced in animals. Similar bacterial emboli were not found in the capillaries of the lungs, liver, spleen, or neck. The heart and other organs were not examined.

I cannot ascertain that others have alluded to the presence of bacteria in the vasa vasorum. If a frequent occurrence, it would be of importance and may have a relation to ulcerative arteritis. What part the septicæmia played in causing the patient's death cannot be told, because the case was complicated by other bacteria, the presence of which cannot be ignored. In the walls of the renal vessels and in the intertubular tissues there were vast numbers of large bacilli, which in size, shape, and appearance exactly resembled Baumgarten's¹⁰ representation of the bacillus septicus, or Fraenkel and Pfeiffer's microphotographs.¹¹ They grew separately or in long strings (Fig. 23); their ends were slightly rounded, with a width of one millimetre and a variable length, but always

FIG. 23.

Angina Ludovici. Kidney with large bacilli in the walls of the vessels near the hilum; also with small bacteria in the capillaries.

many times the width; they contained no spores, but multiplied by fission; they evidently shunned the blood stream and grew in the interstices of the tissues running parallel to the muscle cells or connective tissue bundles. A similar absence of bacilli from the blood is observed when animals are killed with the bacillus septicus, and is accounted for by its strictly anaerobic properties. But as decomposition ensues they appear, as Flüge says, in the decomposing and oxygen-free blood.¹¹ In this way their occasional presence in the blood in this case would be explained. The secreting substance of the kidney had not suffered in any considerable degree, but the interlobular connective tissue was swollen, with here and there small inflammatory exudations, amidst the cells of which were occasional cocci, diplococci, and streptococci.

Before discussing the meaning of these large bacilli I propose to describe their presence in other organs. The lungs had the usual histological characters of acute septic broncho-pneumonia. (Fig. 24.) Their vessels were engorged with blood, forming a natural injection. This blood contained a few large bacilli, the same as those in the tissues of the kidneys. But the walls of the smaller pulmonary veins, like the renal veins, contained considerable numbers. The solidified pneumonic tissues were packed with vast numbers, and they were particularly abundant beneath the pleura and

⁸ I am indebted to Dr. C. Addison for much hard work at this case.

⁷ THE LANCET, March 9th, 1895.

⁹ Ibid.

in "non-vascular areas. They were clearly the predominant feature in the lung disease. In the lungs the bacilli grew in leptothrix less often than in the kidneys. The pneumonic tissues also contained occasional encapsuled diplococci the same as those described by Fraenkel and others.¹² Their presence was unexpected and gives rise to speculation as to their meaning in this and other cases. As Netter, Biondi, Vignal, Fraenkel, and others have shown, encapsuled cocci are found in saliva,¹³ and may thus, it may be supposed, pass into the air passages and lungs. The purulent tissues of the floor of the mouth were packed with cocci, diplococci, streptococci, and bacilli of various kinds. Amongst the cocci the presence of staphylococcus aureus and streptococcus pyogenes was proved by cultures. The bacilli included the ordinary ones of putrefaction, and in addition the sections of the deeper cedematous muscles and cellular tissues of the floor of the mouth and of the neck contained many large non-spore-bearing bacilli, the same as those in the kidneys and lungs. These bacilli were most difficult to demonstrate; but Dr. Addison and myself succeeded by soaking the sections for many days in Czenzynke's solution. Thus this case lends support to Baumgarten's¹⁴

FIG. 24.

Angina Ludovici. Septic pneumonia in angina Ludovici.

statement that acute phlegmon of the submaxillary cellular tissue was an invasion of streptococcus or of staphylococcus pyogenes, sometimes of both together, and to Eisenberg's observation that he found streptococci in the saliva in a case of phlegmonous angina. As Widal and Besançon have recently shown, streptococci are present in the mouth in both health and disease. I do not think, however, that the large bacilli in the floor of the mouth, neck, lungs, and kidneys can be ignored. I was prompted to look for bacilli because some kinds of angina Ludovici have such a close resemblance to acute spreading traumatic gangrene or malignant cedema, a disease which is acknowledged to be of bacillary origin, being caused by the bacillus septicus.

It may not be out of place for me to remark that the bacillus septicus is of the greatest interest to surgeons, and may, as I have already said, occur oftener than is thought. It was discovered by Pasteur and investigated by Koch, and is also called the "bacillus cedematis maligni." The disease which it causes is also called "gaseous or acute spreading traumatic gangrene." The bacillus septicus is an inhabitant of earth, mud, and decomposing substances of all kinds; hence it may be found in the human body without it having caused the fatal disease. In size and appearance the bacillus septicus closely resembles the bacillus of anthrax. Its ends, however, are slightly round, and its spores, which are not formed whilst the bacillus is in the tissues, are large enough to bulge the bacillus; it is also mobile and is a strict anaerobe; it usually produces a quantity of fetid gas. The clinical effects of the bacillus septicus might almost be inferred

from its behaviour in the laboratory. The rapidity of its growth and motion is exemplified by the swift spread of the disease, its abhorrence of oxygen by its passage along the lymph paths, its gas-producing powers by the emphysematous crackling, and, lastly, the noxiousness of its ptomaines by the poisoned condition of the patient. But although the production of a fetid gas is one of the properties of the bacillus septicus, yet Sternberg¹⁵ says that pure cultures often cause inflammatory cedema without emphysema. Very little seems to be known about the behaviour of the bacillus in the human organs. Obviously any gas which it produced in the lungs would escape and leave no trace, and probably the same applies to the kidneys. But in the case which I have just described the escape of gas from the pulmonary veins and its presence in the peritoneal sac are to be noted as evidence of the presence after death of a gas-producing bacillus. Presently I will describe another case of angina Ludovici in which the emphysematous crackling of the skin and subcutaneous tissues was observed during life, and in which there was also a bacillus in the lymph paths and in the inflammatory exudation. (Vide Fig. 26) It has lately been claimed that other bacteria besides the bacillus septicus cause acute inflammatory cedema and emphysema of the cellular tissues. Eugen Fraenkel¹⁶ has described such an one and called it "bacillus phlegmonis emphysematosi." It closely resembles the bacillus septicus in all its characters, but is motionless. It was found in four cases of "gas phlegmon." Bunge¹⁷ in a case of emphysematous cellulitis (gas phlegmon), found the bacillus coli communis and staphylococci, streptococci and proteus together. Rosenbach also observed the coincidence of pyogenic cocci and bacillus septicus.¹⁸ Gärtner¹⁹ has recently described a gas-producing bacillus, which Klein²⁰ considers identical with the bacillus coli communis. I shall soon describe a case of angina Ludovici in which there was emphysema, and in which a bacillus was seen in the skin and cellular tissues. This bacillus had not quite the morphological characters of the bacillus septicus. We must also take into consideration a bacillus which Dr. Klein²¹ met with in the tissues of guinea-pigs inoculated with garden earth. It grew in rods of different lengths and was mobile. Moreover, it was an aerobe and did not liquefy gelatine. In many points Dr. Klein's account of his bacillus reminds one of the colon bacillus, which is of course a common inhabitant of earth which has been manured. The possibility of there being cadaveric bacilli which had emigrated from the intestines has also to be considered. Although I have examined a great many diseases by the same methods similar bacilli have not been met with, except in the case of axillary wound with pleuritis (Fig. 7), and in a case to be described forthwith. Moreover, in the case of which I am speaking the bacilli were always most abundant where there was most disease. In a case of pneumonia due to the laceration of the lung by broken ribs the ordinary picture of a fibrinous pneumonia was unaccompanied with bacilli such as were found in angina of Ludwig and the case of fracture of the jaw which I am about to describe. Indeed, in the traumatic pleuro-pneumonia I could not with confidence assert the presence of any bacteria, although it is probable that a few scattered encapsuled cocci were present. All kinds of methods were used to stain the sections. Great labour was expended in examining the lungs of a patient who died from pneumonia after excision of the tongue. The pneumonic exudation was fibrinous and contained encapsuled bacteria, often in pairs, but no big bacilli. If these bacilli in the kidneys and lungs of this case of angina of Ludwig had been cadaveric it means, of course, that they had grown after death. Therefore I should have expected to have found them elsewhere than in the diseased tissues and organs. But none were found in the spleen or liver, although those are organs which are especially exposed to infection from the bowels. But throughout these investigations I have greatly felt the want of more definite knowledge of the cadaveric bacteria, especially their morphological

varieties and staining properties. Sternberg²³ gives a brief reference to the subject and a photograph of cadaveric bacilli. No resemblance can be traced betwixt these and the bacilli found in the tissues of this case of angina. Jensen and Sand²⁴ also say that many large bacilli are found in animals which have died from asphyxia and lain for twelve or twenty-four hours. They differ from the bacillus septicus, however, in form, microchemical peculiarities, and inoculation effects. It would be no detracton from the importance of these bacilli to acknowledge that they were saprophytes causing putrid decomposition. That, most probably, is their function. But everyone knows that putrid decomposition of the tissues and fluids of the body occurs during life in angina Ludovici, and is part of the disease. Even if we assumed that these large bacilli were the chief cause of death, yet the bacteria which swarmed in the floor of the mouth may have played an important rôle. For the life of strict anaerobes like the bacillus septicus and its congeners oxygen must be either absent or abstracted. Now, many of the saprophytic and pyogenic bacteria, such as those in the foul tissues of the floor of the mouth, consume oxygen with avidity, and prepare and maintain an environment in which the anaerobes can live and flourish. Nothing was found at the necropsy or before to show whence these various bacteria came. It is to be doubted whether normal saliva could produce such effects, although it is well known that it often contains pathogenic bacteria. The important part which the saliva plays in rabies has led to many investigations of its properties by Pasteur and others. Injected into rabbits it causes a rapidly fatal septicæmia, with encapsuled cocci in the blood of various organs;²⁵ but I cannot ascertain that the bacillus septicus has ever been met with in sputum septicæmia. Biondi²⁶ injected the saliva of diseased and healthy individuals into the tissues of bloodvessels of rabbits, guinea-pigs, and dogs. From these were isolated bacillus salivarius septicus, coccus salivarius septicus, micrococcus tetragonus, streptococcus septopyæmious, and staphylococcus salivarius pyogenes, but nothing comparable to the bacillus which abounded in this case of angina Ludovici; but the bacillus septicus is so widespread that there is no difficulty in understanding that it might easily have been introduced with some article of diet.

The foregoing suggests that in future cases of angina Ludovici a determined attempt should be made to disinfect the floor of the mouth and tissues of the neck before septicæmia or general tissue infection has supervened. Solutions of peroxide of hydrogen would probably be the safest disinfectant.

CONVEYANCE OF INFECTION BY CONTIGUITY; SEPTIC PNEUMONIA.

CASE 20 (Fig. 25).—A bacillus morphologically the same as that met with in the tissues of angina Ludovici was seen in the walls of a putrid abscess of the lung, which was found under the following circumstances. A young man who had been intemperate for two years was admitted into St. Bartholomew's Hospital after a brawl suffering from wounds about the head and face, a compound fracture of the lower jaw, and concussion of the brain. The day after admission his urine contained a cloud of albumen. He was very restless and had a temperature of 102° F. He was unconscious, but shouted at intervals. His right arm seemed rather weaker than the left, but this went away, and he became conscious and seemed to be progressing towards recovery. The eleventh day after the injury his temperature rose gradually to 101.8° F., and he again became unconscious with fresh symptoms of hemiplegia. During the ensuing week there was no abatement of these symptoms, and as his temperature still ranged between 100° and 102° he was supposed to have pyæmia, and a cerebral abscess was suspected. His brain was exposed after the skull had been trephined, but nothing was found. Death ensued the day after the operation, and twenty-four days after his injury. At the necropsy the brain was normal. There was suppuration around the fractured jaw with about two drachms of fetid pus. The internal organs were congested, but otherwise normal, except the right lung, which was pneumonic, with a putrid abscess in the upper lobe. It was surmised that this abscess was pyæmic. The

histological examination did not bear out the supposition that pyæmia had anything to do with his death. The liver and kidneys had suffered from his intemperance. In the liver there was an excess of fibrous tissue and in the kidneys commencing interstitial nephritis. The only change which might have indicated sepsis was slight cloudy swelling of the renal epithelium. No bacteria could be found in either the liver, kidneys, or spleen. The lungs, however, afforded abundant evidences of bacterial invasion. They were engorged with blood which had extravasated into some of the air cells, but the latter were mainly filled with pneumonic exudation. In some parts this exudation contained swarms of a small, short, round-ended bacilli (Fig. 25) similar to the

FIG. 25.

Septic pneumonia following a compound fracture of the lower jaw.

proteus vulgaris of Hauser; but the most striking objects were very large bacilli scattered in numbers both in the tissues of the lung and in the pneumonic exudations. These bacilli had slightly rounded ends and were 1 μ thick and from 3 to 6 μ long. They contained no spores and multiplied by fission, being often seen in twos or in short chains. The bacilli were abundant where there was most connective tissue, as, for instance, in the adventitia of the pulmonary vessels, thus suggesting that they were anaerobes. The walls of the obliterated air cells contained many of them, also the exudation; but the blood in the vessels contained none or occasional isolated examples. The lungs contained no bacterial emboli, nor could bacteria be seen in the clots in the vessels. By an unfortunate omission I obtained none of the brain for examination. It may be remembered that the clinical symptoms were like those of cerebral compression, although none existed. None of the bacteria in this lung possessed capsules, but the specimens had been hardened in alcohol. They bore no likeness to Friedländer's pneumo-bacillus, although in animals it seems as if that organism might grow to some size and length.²⁷

THE LOCAL INFECTION IN ANGINA LUDOVICI.

CASE 21 (Fig. 26).—The local tissue changes and some of the characters of the infective process in angina Ludovici were seen in a case which Dr. E. Valentine Gibson²⁷ described. I am indebted to him and Dr. Cameron for some of the inflamed cellular tissue of the neck. Unfortunately, specimens of the other organs could not be obtained. The case was that of a man aged forty-nine years, who had been a heavy drinker, was attacked with cellulitis of the neck, and died comatose in less than fifty-two hours. Twenty-four hours before he died a sudden dyspnoea nearly ended his life, but he was saved by tracheotomy and incisions, and afterwards there was no obstruction to the entrance of air. Nevertheless, his dyspnoea increased and he became

²⁸ A Rapidly Fatal Case of Angina Ludovici. THE LANCET, June 3rd, 1893.

cyanosed before he died. The cellulitis spread from the neck to the chest and, as it afterwards appeared, to the mediastinal cellular tissue. The swollen tissues were full of gas and began to crepitate. The temperature was in no way remarkable and was usually about 98° F., but rose to 101° the evening before he died. The urine contained no albumen. At the examination, which was made four hours after death, an ulcer was found upon the side of the neck, and it is probable that this is the point of inoculation. The inflamed cellular tissue was full of fluid, had a gelatinous appearance, and minute bubbles of gas made it glisten. The mediastinal cellular tissues were also inflamed, but the thoracic and abdominal viscera had nothing noteworthy the matter with them, nor was there any disease of the salivary glands. No bacteria were found in the fluids squeezed from the tissues, and Dr. Cameron reported that he could find "no specific pathogenic micro-organisms in the tissues." By using Czenzynke's method and by staining the sections for many days we found the cellular interspaces and lymph paths crammed with cocci, diplococci, and streptococci in long and short chains. (Fig. 26.) In some places the micro-

FIG. 26.

Angina Ludovici. Streptococci and bacilli in the cellular tissues.

cocci lay in dense masses. The tissues were cedematous and their connective tissue bundles swollen. In some places nests of pus cells had collected, and amongst them were numbers of bacilli. Some of these were about the size of the bacillus anthracis, but with rounded ends. They contained no spores, and were straight or slightly curved. Others were of the same thickness, but shorter. These probably belonged to the same species as the long ones. Finally, the pus had small bacteria in it, of which some were undoubtedly micrococci, but others looked like very small oval bacilli, such as were found in the capillaries of the last case of angina Ludovici.

The discovery of streptococci in this case is quite in accordance with that which others have observed. They probably belonged to one of the species of streptococcus pyogenes. The presence of the large, round-ended bacilli is of great interest when we recall the fact that during life and after death gas was found in the tissues. This might suggest that the bacillus septicus was present. This would not only explain the emphysema, but also the speed with which the patient died. The size and shape of the bacilli do not, however, agree with the assumption that they were the bacillus septicus. They were only half the usual size of that bacterium, their ends were more rounded, and they did not grow in strings. They were much more like some form of bacillus coli communis. As I have already said, both this and other bacilli can cause emphysema and inflammation of cellular tissues. The coexistence of the streptococcus pyogenes with the bacilli affords food for reflection. In cutaneous erysipelas and cellulocutaneous erysipelas streptococci growing by themselves do not often cause a fatal ending. Nevertheless,

the streptococci in this case may have played an important part by producing that absence of oxygen, and perhaps supply of toxins, which the bacillus septicus and the rest of its family require for their proper growth. It is obvious that the conditions would be much more favourable for the growth of the bacillus septicus or similar anaerobes if the tissues were packed with oxygen-loving bacteria, like the streptococcus pyogenes. Farther, we might speculate whether an excessive consumption of alcohol may not also help to produce similar favourable conditions. It is, I believe, supposed that alcohol uses up oxygen, which would otherwise go to the tissues.

CONSECUTIVE INFECTION: THE PATHOLOGY OF HECTIC FEVER.

When septic infection occurs during the course of other diseases, its effects, being confused with those of the original disease, are often overlooked or wrongly attributed to other causes. Thus in the course of tuberculous affections, such as chronic tuberculous arthritis or tuberculous caries, a newly-formed sinus or an ill-advised incision is often the starting-point of a new infective process, which is most destructive to the tissues previously deteriorated by the tuberculous inflammation. Locally, the effects of the new septic infection are often attributed to the original disease, and after it has become generalised the septicæmia is not usually, I believe, recognised as such. The symptoms which accompany it are designated "hectic fever," a phrase unrepresented by any definite morbid anatomy. When septic infection is implanted upon an already established morbid process I propose to call it "consecutive infection." The following is an instance of it both in its local and in its general manifestations.

CASE 22 (Fig. 27).—A young man had suffered for many months with tuberculous arthritis of the knee. A peri-articular abscess formed and was opened. It extended deeply towards the joint, but was not known to communicate with it. This opening ultimately healed, but the knee became stiff and bent. The joint was straightened without apparent ill-effects, but soon after the patient was readmitted, and it was clear that a septic arthritis had been engrafted upon the chronic tuberculous arthritis. The usual local and general symptoms existed together with others, which pointed to breaking-down tuberculous disease of the lungs. There was also an unusual feature in the case. His urine had hitherto been normal, but now a very large quantity, of low specific gravity and containing albumen, was passed. The patient died, it was supposed, of hectic fever and exhaustion, with amyloid disease. Afterwards I found an incision on the inner side of the knee, by which a finger could be passed into the joint. The synovial membrane was tuberculous and thickened, and there was complete erosion of the articular cartilages, with caries and necrosis of the tibia, especially near the outer condyle. The lungs were tuberculous and breaking down, with engorgement of the lower lobes. There was also tuberculous ulceration of the cæcum and right colon. The spleen, liver, and kidneys were enlarged and amyloid, and in addition the kidneys had the naked-eye appearances of parenchymatous nephritis; indeed, they were afterwards used at the morbid histology class to demonstrate that not infrequent combination of parenchymatous nephritis and amyloid infiltration.²³ But an investigation by Gram's method of staining threw fresh light upon the morbid condition; interspersed throughout the cortex of the kidney were numerous bacilli, singly and in chains, also cocci and diplococci, and capillaries blocked with micrococci. So far as the cocci are concerned these appearances were the same as those which are experimentally produced by the injection of cultures into the veins of rabbits. By the eosin and methyl-blue method of staining the capillaries blocked with micrococci were conspicuous objects, mainly situated beneath the capsule of the kidney (Fig 27). Although not quite sure, I thought the emboli were probably composed of streptococci. The bacilli were sparsely scattered and were apparently post-mortem in origin.

The foregoing was, as I have said, considered a typical instance of hectic fever, but whatever that may be there is no doubt but that the youth had septicæmia. Long before this, in 1889, I endeavoured to solve this question of hectic fever being in reality a symptom of septicæmia by inoculating gelatin, agar agar, and serum from the blood of patients with hectic fever. The blood was taken in the usual way from the finger and with the usual precautions. The result

²³ Ernst Ziegler: Text-book of Pathological Anatomy, Part 2, p. 58. Translated by D. Macalister. 1886.

was negative in the case of a man aged twenty-two years with tuberculous disease of the hip of four years' duration and with abscesses; also in that of a youth aged nineteen years, who had had morbus coxae since the age of six. In spite of this failure, I think that this line of investigation ought to be followed up and extended. Indeed this has recently been done, for the occurrence of a mixed infection in tubercle of the lungs has been signalled by Jakowski.²⁹ He investigated the blood during the hectic stage by cover-glass preparations and cultures. Two out of nine cases gave negative results. In two staphylococcus aureus was found, in two streptococcus pyogenes, in two staphylococcus aureus and albus together, and in one streptococcus pyogenes and staphylococcus aureus. The same point has been written upon by Petruschky,³⁰ who remarks upon the frequent coexistence of streptococci and tubercle bacilli in sputum and pulmonary tuberculous abscesses. He attributes secondary infection to these streptococci, and advocates early diagnosis and early treatment of the primary tuberculous disease. Although it is well known that tuberculous processes are often complicated by the presence of other kinds of bacteria hardly anything has been written

are in themselves able to cause marked rises of temperature, as was seen during the attempt to treat tuberculous diseases with Koch's tuberculin. Although the foregoing mainly refers to consecutive infection in tuberculous diseases, there is, I think, no doubt but that it may occur after any form of infective disease which produces the necessary conditions. Amongst these it is probable that typhoid fever ought to be included. That disease sometimes seems to terminate by the superaddition of a septicæmia, the blood becoming infected through the intestinal ulcers.

TEN FATAL CASES OF ACUTE IDIOPATHIC CEREBRO-SPINAL MENINGITIS.

By J. A. ORMEROD, M.D. OXON., F.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL; PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE, W.C.

FIG. 27.

Hectic fever. Micrococcus emboli in the capillaries of the kidneys. The kidneys were also in a state of parenchymatous inflammation with amyloid disease.

about their presence in the circulation. Mr. Watson Cheyne³¹ has mentioned a case in which he found micrococci in the vessels of tuberculous patients. He did not at that time lay much stress upon them, but said, "though quite independent of the disease, [they] probably hastened the death of the patient, or they may have been present simply as the result of lowered vitality, though in that case I have never found them as plugs in the vessels." Cornil and Babes in a case of tuberculous caries of the spine found vessels filled with streptococci.³² The same microbe was also found by them in the pulmonary glands, peritoneum, and meninges of other cases of tuberculosis. Koch³³ has described a case of acute general tuberculosis in which many capillaries were blocked for a short distance by micrococci. He thought that a mixed infection of this kind would, if looked for, be found tolerably often. Much work remains to be done before we shall know whether the phenomena of hectic fever are always due to a consecutive infection. The ptomaines of tubercle bacilli

Acute cerebro-spinal meningitis, for which no obvious cause can be found, is not on the whole a common disease. Ten fatal instances of it occurred at St. Bartholomew's Hospital during the six years that I was medical registrar there (1887-1893), and the physicians kindly gave me leave to publish a short account of them. All cases are excluded wherein any recognised cause could be found, such as tubercle, injury, otitis, disease of the skull-bones, pyæmia, ulcerative endocarditis, pneumonia, erysipelas, &c., and also those in which only the cerebral membranes were affected (though doubtless some of these do not essentially differ from the cerebro-spinal cases) or in which post mortem the examination of the cord was omitted. In addition to the ten fatal cases there were three (or perhaps four) cases during the same period which recovered. Unfortunately, I can give no sufficient account of the bacteriology of these ten cases, which to many may seem their chief point of interest; but in a subsequent case occurring since my term of office Dr. Kanthack¹ demonstrated the presence of the pneumococcus; and our present registrar, Dr. Herringham,² notes that this organism has been found in two other recent cases. This, I believe, is in accordance with the majority of bacteriological observations on the subject. Nor have I anything to say as to their etiology generally, save that one case (No. 4) developed meningitis in the course of some acute throat affection, and four out of the ten (of which No. 4 was one) occurred between March and June, 1890. This is an unusual number for such a short time, and the fact suggests the possibility of some epidemic influence. As a matter of fact, an epidemic of meningitis did occur in the summer of that same year in the Eastern Counties.³ It is, indeed, possible that idiopathic meningitis does not differ essentially from the epidemic disease. The clinical resemblance may be illustrated by a case admitted under Dr. S. J. Gee in October, 1892. A child had been seized with vomiting, fever, and delirium; on admission she had retraction of the head, and a papular and petechial rash, with some larger purpuric spots. Later she developed a purulent infiltration of one eye, leading to its complete disorganisation, and arthritis in the knee; finally, she recovered, and was discharged after being four months in the hospital. This might serve as a picture of epidemic cerebro-spinal meningitis, but there was no epidemic.]

The cases that follow are given in chronological order. The clinical notes are taken from the records in the ward-books; the notes of post-mortem examinations, except where indicated, were my own work.

CASE 1.—(The onset took place with a fainting attack, then pains in the head, mental alteration, noisy state, and fever. Thereupon strabismus supervened, and finally coma, with Cheyne-Stokes breathing. Death took place in five days.) The patient was a boy aged six years, and was placed under the care of Dr. W. S. Church in the Matthew Ward in April, 1890. He was in his usual health till April 15th, when he was brought to the surgery for circumcision, but the operation was deferred because he fainted whilst walking across the hospital square. The next night he had pains in the head, strangeness

of manner, drowsiness, and diarrhoea. He had measles two years before, with diarrhoea. On the 16th he lay on his back, putting his hand to his forehead as if in pain, the temperature being 103° F., with hot, dry skin; the pulse 144, regular and soft; and the respiration 36. On the 17th he was restless and noisy all night, screaming as if in pain, and putting his hands to his head. The temperature in the morning was 100°, and in the afternoon 103°. On the 18th he had a very bad night, shouting much, though conscious. There was internal strabismus of the right eye; the fundus of both eyes was normal. The temperature in the morning was 104°, and in the afternoon 103.8°. On the 19th he passed a very restless night. He had now double internal strabismus. The temperature was 102.8°. At 2.40 P.M. he was quite unconscious, with Cheyne-Stokes respiration; the pupils were contracted, and the strabismus had gone. The pulse was 135, but otherwise good. He died on the same day.

Necropsy.—There was sticky greenish-yellow lymph beneath the cerebral arachnoid, alike upon the convexity and the base (upon the former mainly in large patches and at the latter on the olfactory bulbs, optic commissure, and behind it); in the Sylvian fissures, where the membranes also looked thickened; and a small patch on the cerebellum. The convolutions of the brain were flattened, the surface was pale, and much turbid brownish fluid escaped during removal. Similar turbid fluid was present in the sac of the spinal dura mater, and in the spinal arachnoid there was thick yellow lymph, mainly upon the posterior surface of the cord. The cervical region was free, the deposit of lymph beginning in the upper dorsal region, and increasing in amount from thence downwards. There was some softening of the dorsal and lumbar cord. Except for a swollen gland at the left angle of the jaw (non-tuberculous and not caseating) and some œdema of the lungs, there was no other disease in the body.

CASE 2.—(The onset occurred with vomiting, petechial rash, headache, and screaming. There was herpes labialis on the third day, followed by strabismus and retraction of the head. Some improvement took place after a week's illness; but the patient became apathetic and wasted much. In the third week there was recurrence of the vomiting, the head was retracted, the knee-jerks were absent, and death took place about the twenty-fifth day. This case was complicated with whooping-cough. Post mortem there were found cerebral and spinal meningitis and much ventricular effusion.) The patient was a boy aged five and a half years who was under the care of Sir Dyce Duckworth in the Elizabeth Ward of St. Bartholomew's Hospital in March, 1890. The illness began on March 2nd with vomiting and fever. During the following night he woke up struggling and screaming. On the 3rd, at 10 A.M., the mother noticed a red rash on his hands, arms, and face, which in an hour's time had spread to the legs and had turned black. There had been measles in the street where he lived, but this complaint he was said to have had before on two occasions. A younger brother had whooping-cough. The patient had had a cough for a month, which had become worse since this illness. He now seemed to be ill and drowsy, the tongue being furred and the throat normal. There were minute purpuric spots on the face, trunk, and limbs; on the left thigh there were one or two papules; on the left buttock there was a small ulcer with purpuric areola. The temperature was 99° F. On the 4th vomiting occurred in the night and early morning. There was a purpuric spot on one conjunctiva. The pulse was small and very irregular. Some small glands could be felt under the left angle of the jaw. On the 5th vomiting occurred at night. The patient suffered from frontal headache. The purpuric spots had mostly faded. Herpes appeared on the upper lip. The temperature rose during the day to 102°. On the 6th he screamed violently during the night. He appeared to have abdominal pain as well as headache. The vomiting was less at midnight. Internal strabismus was noticed, as well as retraction of the head. The temperature varied from 100° to 101°. During the next few days there was some improvement, especially as regarded the vomiting; but whooping-cough developed. On the 12th the temperature rose to 102.4°, and on the 13th to nearly 103°. On the 13th he lay in an apathetic state, screaming on palpation of the abdomen; he screamed occasionally during the night from the headache. Knee-jerks were absent. On the 16th it was noted that he was becoming much emaciated. On the 24th vomiting recommenced. He lay on his back and side, with the head retracted and the legs drawn up, noticing nothing, but not unconscious. The temperature varied from 99° to 101°; the pulse was 135. He died on the 28th. The

eyes were examined, but nothing more was noted than a slight blurring of one disc, probably physiological.

Necropsy.—In the arachnoid, at the base of the brain, from the optic nerves to the crura cerebri, there was a layer of thick puriform stuff; the Sylvian fissures were gummed together, but no tubercles could be made out, and no tubercle bacilli could be found in the exudation. The convolutions were flattened, the corpus callosum was much thinned out and softened, and the ventricles were much distended with fluid. There was a patch of puriform stuff in one choroid plexus. As for the spinal cord, much fluid escaped on incising the dura mater, the arachnoid was rough, and in the lower dorsal region yellowish lymph was seen. There was much superficial softening of the cord. All the other organs of the body were healthy.

CASE 3.—(There was pain in the head, with hallucinations, vomiting, fever, and ptosis. Herpes of the lips and face supervened on the fourth day with albuminuria. Death took place at the end of four days.) The patient, a boy aged nine years, was admitted to the John Ward under the care of Sir Dyce Duckworth in April, 1890. He was quite well and at school on April 24th, and slept well that night; but on the morning of the 25th he woke up "silly" about 7 A.M., wandering, complaining of pain in the head, saying that "his sight was blighted," and apparently suffering from hallucinations of vision. Ever since he had been partially stupid, particularly during the night, had vomited what he took, and had had some ptosis of the right eyelid. Nevertheless, he was able to come alone to the surgery on the 26th; but as the stupor and headache increased he was brought again at midnight and admitted. The temperature then was 103.4° F. On the 27th he looked ill and flushed, and had an expression of pain. He objected to being examined. He tossed about restlessly, and complained, when asked, of pain in the head and in the back. He saw mousetraps, marbles, and his boy friends, and talked to them. He nevertheless answered easy questions and put out his tongue when asked. The tongue had a patchy fur upon it and was dry. The temperature was 101°, the pulse 140, and the respiration 35. There was partial ptosis of the right eyelid. In the afternoon there was well-marked double internal strabismus; the knee-jerks were natural. There had been some twitching of the right side of the face. The temperature was 104°. On the 28th it was noted that he had had no sleep since admission, being restless and noisy. There was much herpes on the lips and cheeks. The temperature was 100° (rising to 103° in the afternoon), the pulse 116, and the respiration 40. The urine was of sp. gr. 1026, and contained no sugar, but much albumen. During the next night the temperature fell to 98° and then rose again rapidly to 105°, after which he died.

Necropsy.—On the convexity of the brain, along the course of the veins, there was yellow, purulent lymph in the meshes of the pia-arachnoid. There was lymph at the base also, but less in quantity. The brain was reddened and softened on the surface. The cervical part of the spinal cord was superficially reddened, but there was no lymph. At the upper dorsal region a layer of lymph began and thence continued downwards, getting thicker near the lumbar region. It was limited to the posterior surface of the cord. In appearance the lymph was thick and purulent. There was some slight softening of the dorsal cord. The dural sac contained some dirty fluid. Except for some trivial swelling and reddening in the arytenoid region of the larynx and a slight enlargement of the mesenteric glands, all the other organs were normal. The appearance and distribution of the lymph in the cerebral membranes did not suggest tuberculous meningitis; no tubercle could be seen by the naked eye, and Mr. Edgar Willett, who kindly examined the spinal lymph microscopically, could find no bacilli in it.

CASE 4.—(On the fourth day of an acute inflammation of the fauces headache set in and albuminuria, with recurrence of fever. On the fifth day the headache was worse and consciousness was impaired; then there was a rigor, followed later by hallucinations of vision and a restless, tremulous state. On the sixth day there was laryngeal obstruction (œdema?), which was relieved by tracheotomy, after which occurred coma, conjugate deviation of the eyes, twitching of the arms, Cheyne-Stokes breathing, and hyperpyrexia. Death took place about forty-eight hours after declaration of the nervous symptoms.) The patient, a man aged thirty-eight years, was admitted under the care of Sir Dyce Duckworth into the Radcliffe Ward, St. Bartholomew's Hospital, in June, 1890. On the morning of June 19th he was taken ill

with vomiting, sore-throat, difficulty of breathing, and pain in swallowing, and a swelling developed in the right side of the neck. The same evening he came to the surgery looking very ill, the temperature being 103.5° F., the pulse 140 and feeble, and the respiration 36 and stridulous. The fauces, right tonsil, and the right side of the palate were cedematous, and no membrane was to be seen. Scarification was performed with some relief. He stated that his previous health had been good; he knew of no diphtheria in his neighbourhood, but the drains were said to be bad where he lived. On June 20th he was admitted to the Radcliffe Ward. His neck was swollen, especially on the right side; the fauces were also swollen, especially on the right side, and generally reddened, except the uvula, which was pale and thickened. There was a doubtful appearance of membrane on the right side of the fauces (which seems not to have been confirmed later). The temperature was 99.8°, the pulse 99 and of good volume and tension, and the respiration 16. The urine contained no albumen. Till the evening of the 22nd he progressed favourably, and the faucal inflammation went down considerably. The temperature was normal in the early morning, but in the course of the morning it rose to 102.8°, and at 7 P.M. to 104.8°. He had some headache all day, which became worse towards night. The tongue was much furred. The urine contained one-third albumen. On the 23rd, since 2.30 A.M., he was restless, with violent pain in the head, and only partly conscious. He had a rigor in the early afternoon, the temperature, which had been 102° in the morning, mounting to 104°, the heart's action being feeble and irregular. At 6.15 P.M. he had hallucinations of visions, trying to get out of bed, and picking at the bed-clothes; his hands were tremulous, and the tongue was dry, furred, and tremulous. On the 24th he had a sleepless night. There was twitching of the tongue and limbs, with some cedema of the fauces, and poor entry of air into the lungs. In the course of the day urgent laryngeal symptoms set in—stridor, recession, blueness, &c.—for which tracheotomy was performed about midday with considerable relief. At 2.30 P.M. he had been apparently sleeping since the operation; there was conjugate deviation of the eyes upwards and to the right; the breathing was of the Cheyne-Stokes type; the pulse was small and flickering, and the temperature 105.8°. He became worse during the afternoon, had twitching of both arms, and the temperature rose to 108°. He died at 5.50 P.M.

Necropsy by Dr. HAIG.—There was purulent meningitis, most marked on the convex surface of the brain and over the frontal lobes, extending also into the transverse fissure and to the velum interpositum. There were similar changes, but much less marked, at the base, round the medulla, and in the Sylvian fissures. The cerebral ventricles contained some slightly turbid, non-purulent fluid. There was some spinal meningitis, becoming evident at the lower part of the cervical enlargement and extending down to the cauda, being most marked on the posterior surface of the cord. In the larynx comparatively little was seen to account for the dyspnoea, but there was some cedema both of the false and true cords. There was no membrane. The heart weighed 15 oz.; the muscle substance was pale and showed fatty changes; the left ventricle was somewhat dilated. The spleen weighed 11 oz. and was soft and pulpy. The liver weighed 66 oz. and was normal in appearance. The kidneys weighed 18 oz. the pair; they were generally enlarged, the structure of their cortex being somewhat blurred; the capsule did not peel well—probably there was some increase of fibrous tissue. The other organs were natural.

CASE 5.—(Rigor followed by headache; in four days' time delirium, then coma, rotation of head and eyes to the left; albuminuria; death on the seventh day.) A man aged thirty-nine years was admitted into the Mark Ward of St. Bartholomew's Hospital under the care of Dr. Andrew in January, 1891. On Jan. 3rd, at noon, having been previously quite well, he shivered and could hardly get home. Since that time he had been in bed, complaining of his head, and had vomited once. On the 5th he shivered for hours, became hot afterwards, and sweated. On the 7th he was light-headed. On the 8th (after admission) he looked ill, with the face drawn and black sordes on the lips. He was delirious and restless; his breathing was noisy, 44; and the temperature was 102.5° F. The tongue was dry, with brown fur; the eyes deviated to the left. He lay with his head to the left, and seemed inclined to roll to that side. He did not understand or answer questions. On the 9th he was comatose and passed faeces in the bed; the urine (drawn by catheter)

contained albumen, but no sugar. His breathing was rapid, his colour more blue, the pulse 160 and very weak, and the temperature 101°. He died on the same day.

Necropsy.—In the subarachnoid space of the brain there was a thick layer of yellowish-green, purulent lymph covering the convexity of the brain on both sides. The same was observed in the interpeduncular space, over the surface of the cerebellum, and in the Sylvian fissures. The brain itself was normal. There was much lymph, like that on the brain, along the whole length of the spinal cord, except in the cervical region, where the membranes were only injected. The lymph was most abundant on the posterior aspect of the cord, though present on the anterior aspect also. The heart weighed 15½ oz., the left ventricle was thickened, but the valves were normal. The right suprarenal was cystic, consisting of a thickened, reddish wall, enclosing a cavity full of thick fluid. The left suprarenal could not be identified, and there was much hard, yellow fat in its place. The right kidney was rather small, pale, and soft; the left kidney was in its lower part like the right; in its upper part the renal substance was thinned and atrophic, and the capsule was very thick. The spleen was large, soft, and wrinkled.

CASE 6.—(There were vomiting and strabismus for about a fortnight before admission; after admission there were drowsiness, retraction of the head, and occasional strabismus, but no fever. The patient died about a month from the commencement of the symptoms. There was meningitis of the cord and the base of the brain and much hydrocephalus.) The patient, a female infant aged six months, was admitted into the Hope Ward of St. Bartholomew's Hospital under the care of Dr. Andrew in February, 1891. She was well till Jan. 1st, but had since then suffered from cough and loss of flesh. She had vomited during the last fourteen days, strabismus occurring about the same time. On Feb. 19th (when she was admitted) she looked very pale and the lips were rather blue. She was drowsy, the head being retracted and the eyes staring; there was slight internal strabismus at times. The temperature was subnormal and the pulse feeble and irregular. The optic discs were not quite clear, but there was no definite neuritis. The subsequent notes indicate very little change. The head was usually retracted; there was strabismus from time to time; the pulse was frequent, feeble, and irregular, and the temperature was normal or subnormal. On March 3rd the patient died.

Necropsy.—Beneath the cerebral arachnoid there was a very thick deposit of greenish lymph in the interpeduncular space; the Sylvian fissures were quite free. The cerebral ventricles were enormously distended with clear fluid. A thick deposit of lymph covered the spinal cord also, being most marked in the dorsal and lumbar regions, though visible in the cervical region also. There was no evidence of tubercle, and all the thoracic and abdominal viscera were normal.

CASE 7.—(There was a doubtful history of a blow on the head. The onset occurred with vomiting; there was nocturnal restlessness, and on the next day stupor with restlessness. On admission there was left-sided paralysis and the knee-jerks were absent; the coma was deepening, and death supervened with signs of pulmonary congestion and a tendency to Cheyne-Stokes breathing. There was moderate fever (99.5° to 102° F.). Death occurred on the fifth day.) The patient, a girl aged three years, was admitted into the Elizabeth Ward of St. Bartholomew's Hospital under the care of Sir Dyce Duckworth on Dec. 4th, 1891. On Dec. 2nd, on coming home from school, she said that a boy had hit her on the head. That day she vomited several times, and during the next night was restless, tearing her hair and throwing the bedclothes about. On the next day, Dec. 3rd, she again complained that a boy had hit her on the head. Since then she had not spoke rationally or recognised anyone, but had lain tossing about whining and muttering. On admission she was restless and tossing about. There was no rash and no evidence of injury to the head. She did not seem to notice a strong light. There was no strabismus, the pupils were normal, and there was no optic neuritis. She passed everything under her. There was weakness of the whole of the left side. Neither knee-jerk was obtainable. The plantar reflex was present on the right but absent on the left side. The temperature was 99.5°. On the 5th she was much worse. She lay quietly on her back. There was complete left-sided paralysis, including the upper face. There was conjugate deviation of the eyes to the right and scarcely any corneal reflex. The temperature in the morning was 102° and in the evening 100°. On the 6th, at 3.30 A.M., her complexion was dusky; there were tracheal râles; the respiration was 40,

with a tendency to Cheyne-Stokes rhythm; the pulse could not be felt at the wrist; the heart beats were 156; and the temperature was 102°. She died at 10 A.M.

Necropsy.—There was no sign of injury either to the skull or elsewhere. On either cerebral hemisphere, beneath the arachnoid, and principally on the lateral and upper surfaces, there were large tracts of thick, yellow, purulent lymph. At the base there was some lymph covering the infundibulum and optic commissure, and a little on the under surface. There was none in the Sylvian fissures (till the lateral aspect of the brain was reached), nor were the lips of the fissures adherent. No tubercles were seen, nor did the appearances suggest tuberculous disease. The convolutions were flattened, and the surface of the brain was pale and sticky and bulging through the incised dura mater; yet there was no excess of fluid in the ventricles or any inflammation of the choroid. The sections of the brain were pale and soft. As for the spinal cord, dirty fluid came from within the dural sheath. In the lumbar and lower half of the dorsal region, on the posterior aspect of the cord, there was purulent lymph in the arachnoid, like that on the brain. There was none on the anterior aspect of the cord or on either aspect of the cervical and upper dorsal cord. The nerve roots of the lumbar and lower dorsal regions were red and swollen. The cord itself was somewhat softened at the periphery, but otherwise normal. Coming to the chest, there were one or two oldish adhesions of either pleura. There was reddening and roughening of the left pleura. No pneumonia existed. One small caseous gland was observed at the root of the left lung. The abdominal organs were normal. Dr. F. Andrewes kindly examined the cord for micro-organisms and gave me the following (verbal) report: "No diplococci pneumoniæ. Numerous bacilli, which would not grow in cultures. The only organisms which could be got to grow resembled the streptococcus pyogenes aureus."

CASE 8.—(The patient had had a convulsive fit in the street and was brought in semi-comatose after this. A second fit followed, with persistent coma, deviation of the eyes to the left, and a rise of temperature. Death supervened in about thirty hours.) The patient, aged fifty-two years, was placed under the care of Dr. W. S. Church in February, 1892. On Feb. 17th, while walking in the street, he was noticed by a policeman to fall in a fit. According to the description given there were tonic and subsequently clonic convulsions, with frothing at the mouth. When brought to the hospital (5.30 P.M.) he was semi-comatose and unable to tell his name, or, indeed, to speak. The stomach was washed out; there was no alcohol in it, though it appeared from the statements of his friends that he was a heavy drinker. While being put to bed in the Surgery Ward he had another fit, with clonic contractions and afterwards rigidity. The temperature was then 103.2° F. He remained unconscious all night; there was conjugate deviation of the eyes to the left. The temperature next morning was 105.6°. He was moved to the John Ward. On the 18th he lay unconscious, with the limbs rather rigid; he moved the limbs when stimulated, but not in a purposive way; there were frequent slow movements of the fingers like those of athetosis. The temperature was 102.2°; the respiration was 48 and laboured; the pulse was rapid and of poor volume. The knee-jerks were normal; the plantar reflexes could not be obtained, and he did not swallow well. At 9.30 P.M. the temperature was 104.3°, the pulse was much weaker, and the respiration was more laboured. He died during the same night.

Necropsy.—There were the remains of an old ulcer on the left leg, but it was perfectly quiescent, and the bone beneath it was not diseased. There was a purulent effusion into the subarachnoid space, extending over the whole convexity of the brain; in the anterior half, for some two or three inches from the longitudinal fissure outwards, it formed quite a thick sheet, which could be peeled off. A similar, though less marked, effusion covered the interpeduncular space and the upper surface of the cerebellum. There was none to speak of in the Sylvian fissures. No tubercles were visible. In the choroid plexus of the ventricles there were several small cysts with soft yellowish contents. The brain itself was normal. There was no ventricular effusion. Coming to the spinal cord, there was turbid fluid within the dura mater. Beneath the arachnoid there was a purulent effusion like that on the brain, but more liquid. There was none on the anterior surface of the cord. Of the posterior surface, the cervical region was nearly free, but the whole dorsal region was covered with effusion; the surface of the lumbar enlargement was reddened, but showed no effusion.

The cord itself was natural on section. The apex of the right lung was puckered, containing some fibroid spots and a little grey translucent tubercle. The spleen was very soft and not notably enlarged. The liver was probably fatty. The left supra-renal contained a few small spots of quite doubtful nature. One kidney contained a curious cyst, in which was some slimy stuff having the colour of faeces.

CASE 9.—(The onset occurred with vomiting and headache; the latter was persistent and occipital, and there was pain in the neck, back, and limbs. The neck was stiff and tender. There were slight strabismus and nystagmus, and incipient optic neuritis (?). The patient suffered from wandering at night and tremors of the hands. Death occurred in about twelve days from the onset.) The patient, a young woman, was admitted into the Faith Ward of St. Bartholomew's Hospital under the care of Dr. W. S. Church in November, 1892. A week previously she had had a so-called "bilious attack"—viz., retching, vomiting, and headache—and since then constant occipital headache and gradual onset of pain in the neck, back, and arms. The neck was stiff for three or four days. The bowels had been confined for the last week. On Nov. 29th the temperature was 101.4° F., the pulse 76 and soft, and the respiration 30. The neck was stiff. There was tenderness over the third and fourth cervical vertebrae, and the hands were tremulous. There was slight internal strabismus. There were jerky lateral movements of the eyes on fixing any object. The urine showed a cloud of albumen (which cleared up, however, the next day). On the 30th she had a sleepless night, with much wandering, the temperature rising to 103.6°; in the morning it was 102.6° to 103.8°. The tongue was red and angry; there was a fleeting erythema about the chin and face; the hands were more tremulous, and the neck was still tender. During the next few days there was little change, save that the temperature fell somewhat (102°, 100°, 98°), while the pulse became more frequent on the whole. The abdomen became distended. The fundus of either side exhibited some old patches of choroiditis; the discs were ill-defined and woolly, but did not exhibit distinct optic neuritis. She died on the evening of Dec. 4th.

Necropsy.—There was found a large thrombus in each branch of the pulmonary artery; there was a little scanty lymph on the left pleura, with ecchymotic spots on the pleura, and there were two small infarcts in the left lower lobe. There was meningitis at the base of the brain—viz., a well-marked layer of thickish lymph covering the pons Varolii. Coming to the spinal cord, a well-marked layer of greenish-yellow lymph covered the posterior surface of the dorsal and lumbar regions. The arachnoid elsewhere—viz., in the cervical region and on the anterior aspect of the cord—was rather difficult to separate from the cord and perhaps a little thickened; but the meningitis as a whole was an acute process.

CASE 10.—(There was a history of headache and general pain, the patient a day later being found unconscious in the street. He made a very partial recovery, right hemianæsthesia ensuing. Later another fit occurred, followed by right facial palsy (!) and retraction of the head. Death supervened in about three days from the first symptoms.) The patient, a man aged fifty years, was admitted into the Mark Ward of St. Bartholomew's Hospital under the care of Dr. Andrew in February, 1893. It appeared that on the night of Thursday, Feb. 2nd, the patient had complained of headache and pains all over him. Nevertheless he took breakfast the next day and was supposed to have gone to work as usual. Nothing more could be found out about him till the evening, when he went into a coffee-house where the people thought him a little strange in manner. Next he was found in the road near the coffee-house, quite unconscious, some slight convulsive movement of the right hand being noticed. On being brought to the hospital (about 8 P.M.) he recovered consciousness to a limited extent and managed to raise himself and stand up, but did not answer when spoken to and only looked up with a dazed manner. He appeared to have less power in the right arm than in the left. His right conjunctiva was less sensitive than the left. He constantly put his left hand to his occiput. The temperature was 97° F. A pint of urine was drawn off, containing a considerable amount of albumen. He was put to bed in the Surgery Ward. His temperature rose to 101°; the pulse was regular and of moderate frequency; the respiration was unembarrassed, but irregular, being sometimes shallow, sometimes deep. He was found to have right hemianæsthesia. He passed his urine into the

bed. He was restless all night, but not violent, or quite unconscious of his surroundings. During the next day (Feb. 4th) he did not alter materially, except that he noticed a friend and seemed to recognise her. On the 5th, at 3 A.M., there was twitching of the left arm and face, with stertorous breathing. At 11 A.M. the face was drawn to the left. The right eye did not close (right facial paralysis). Retraction of the head set in, and the knee-jerks were found to be increased. The temperature rose from 100.2° in the morning to 104.4° at midnight, and he died early on the 6th.

Necropsy by Dr. H. M. BOWMAN.—Under the cerebral arachnoid, all over the convexity, there was a considerable amount of turbid fluid. The same was observed at the base, extending over the pons and lower surface of the medulla and about two inches up the right Sylvian fissure, which was rather glued up. As for the spinal cord, the dura mater was healthy, but on opening it there was found to be a considerable amount of pus beneath the arachnoid and an excess of turbid fluid; this condition extended down as far as the cauda equina. At both apices of the lungs there were dense fibrous adhesions, there being calcareous deposits in either apex, with fibroid thickening and puckering. The heart was large and flabby and weighed 14½ oz.; the right ventricle was much dilated. The spleen was small and healthy. The kidneys were large, weighing 8 oz. each; the capsule separated badly, tearing the cortex, but the section of the kidney looked healthy. No pus was found in any joint.

Remarks.—The symptoms in these ten cases may be summarised as follows. Pain in the head was complained of by all those patients who were not too ill or too young to complain; pain in the back twice, in the limbs once, and in the abdomen once. There was fever of variable degree in all cases save one (Case 6), which did not come under observation at the outset. There was no special type of fever. One case (Case 4) terminated with hyperpyrexia; a rigor is mentioned twice only. Vomiting occurred in five cases, and usually at the commencement of the illness. Retraction of the head developed, either a few days after the onset or at a later stage, in three instances, and a stiff neck (probably a minor degree of the same thing) once; rigidity of the limbs was observed only once or twice. Twitchings of the limbs, face, or tongue occurred about four times; actual convulsions only twice. The state of the knee-jerks, examined in five cases, was: absent twice, exaggerated once, and normal twice. Strabismus was frequent, occurring four times—sometimes early, sometimes late; ptosis occurred once, and doubtful nystagmus once. The fundus oculi was examined five times, and twice only was there a (doubtful) optic neuritis. There was no conjunctivitis, iritis, or panophthalmitis (as in Dr. Gee's case quoted above), and no otitis, deafness, or vertigo. As to paralyses, conjugate deviation of the head or eyes (whether this was paralytic or spasmodic) was observed four times, hemiplegia once, hemianæsthesia once, and doubtful facial paralysis once. Mental symptoms were frequent. There was restlessness or irritability in four cases, noisiness or delirium in three; there were hallucinations of vision in two cases, and drowsiness occurred sometimes. Early coma occurred twice. The pulse was usually frequent, being irregular in three instances. The respiration before death was apt to become irregular or to assume the Cheyne-Stokes type. Abnormal states of the tongue (red, dry, furred, &c.) are noted four times, diarrhoea is noted once, and constipation once. No mention is made of a *tache cérébrale*. In one prolonged case (Case 2) there was marked emaciation. Albuminuria occurred four (or, counting a transient appearance, five) times; but in three of these cases the state of the kidneys was questionable. Glycosuria did not occur; but that it may do so is shown by a case of (cerebral) meningitis admitted under the care of Sir Dyce Duckworth in 1891. A man was brought in comatose, his urine being loaded with sugar; diabetic coma was therefore suspected, but post mortem he was found to have purulent meningitis.⁴ As to eruptions, a petechial rash was seen once (Case 2), a "fleeting erythema" once, and herpes facialis twice. The ages of the patients varied from six months to fifty-two years. Thus the commonest features of the disease were: fever of sudden onset and without obvious cause, headache, vomiting, restlessness, and even delirium, and soon afterwards strabismus and retraction of the head, and, finally, death, which was often preceded by irregularity of respiration

or by coma, within a week. But some cases lasted longer—e.g., one for twelve days and two (Cases 2 and 6) between three and four weeks. In both of these latter hydrocephalus was found post mortem; possibly in Case 2 the recurrence of vomiting was the clinical indication of this. Further, as above mentioned, three, or perhaps four, cases (not included in these ten) recovered. In Case 8 the sudden onset, early coma, and rapidly fatal course (thirty hours), without the development of diagnostic symptoms, reminds one of the "type foudroyante," described by writers on epidemic meningitis. A clinical relation to other diseases only appears twice. In Case 2 the patient had whooping-cough, and had been exposed to measles; and in Case 4 the meningeal symptoms developed during an attack of acute faucial and laryngeal mischief, both diseases being possibly the result of some one unrecognised infection. Only one or two remarks need be made about the post-mortem examination results. Pneumonia was never found; pleurisy (in one case with pulmonary infarcts) twice only; the spleen was enlarged only in two instances, and in these the enlargement may have depended on other causes than the fever (Cases 4 and 5). As to the meningitis itself, the purulent character and the distribution of the cerebral exudation sufficed to distinguish it from tuberculous meningitis; the spinal exudation, though sometimes enveloping the whole cord, usually affected the posterior surface chiefly, and the dorsal and lumbar regions rather than the cervical.⁵ Hence, to exclude a spinal meningitis it is not enough to look around the foramen magnum, or even at the cervical region of the cord, but the whole length of it must be examined.

SURGEON IN ORDINARY TO HER MAJESTY THE QUEEN IN SCOTLAND;
SURGEON TO THE ABERDEEN ROYAL INFIRMARY.

I COULD have wished before publishing the method of treating pyloric stricture without operation, with which this communication deals, that further experience of its efficacy had been obtained beyond that which it is in my power to offer. But in my experience non-malignant stricture is rare, and to wait for fresh cases on which to try it might entail almost indefinite delay. I have accordingly decided to make it known as it now stands, that it may, if they think well of it, be tested by others. It is now twelve years or thereby since Loreta drew attention to this stricture of the pylorus by his proposal to treat it by opening the stomach in front, introducing the forefinger into the wound and insinuating it into the stricture so as to expand it from within. The operation was a good deal practised, and with success. But most at least of the cases were only temporarily benefited, as recontraction slowly and surely occurred. And some of the cases were found to be due to the cicatricial contraction of former inflammations and adhesions around and external to the pylorus itself, and hence to be unsuitable for finger dilatation. Mikulicz's improvement upon Loreta's operation, that of incising the strictured bowel longitudinally and suturing the incision so as to form a transverse line of union and widen the bowel, has not been sufficiently tried and reported upon to enable a final verdict to be passed by the surgical profession upon its merits. It probably, however, shares to some degree the objections that are advanced against Loreta's operation. It entails an equal or greater danger to life, and is not suited for every case. In his communication to the Surgical Section of the International Congress at Berlin in 1890 Billroth mentioned that in seven cases he had, for cicatricial stenosis, to excise the pylorus, with the result of four cures and three deaths; to perform partial wedge-shaped excision without complete division in five cases, of which two recovered and three died; while of five cases where the pylorus was not absolutely narrowed, but only twisted by extensive external adhesions, he had in two to introduce the finger and explore by Loreta's method in three,

all dying, the other two recovering after the adhesions, which were less extensive, had been separated. These are rather discouraging results, and it has further to be remembered that many of those who suffer from this stricture are in debilitated and broken health, from the dilated and weakened state of the stomach, and from the attacks of hepatitis and peri-hepatitis that have accompanied or caused the disease. Any method, therefore, that offers a fair prospect of effecting a cure without the risks that an operation entails is worthy of consideration; and such a method, now to be described, I have carefully tried, and from my experience of it am inclined to recommend in suitable cases of the disease. The method suggested itself in the following way. Having had to deal with a few cases of pyloric stricture I was led by the considerations mentioned above to consider whether some safer plan than operation might be devised for overcoming the stricture. Why should a pyloric stricture, or for that matter any non-malignant and therefore cicatricial stricture, of the intestinal tract not be dilated and cured by similar methods to those by which we dilate and cure those of the urethra and rectum? Why not pass through them something that would act in the same fashion as a bougie? It is evident that the passage through the stricture of a hollow viscus in any part of the body of the liquid or pulpy matters it contains does not dilate the stricture from within like a bougie. We have daily evidence of this in the œsophagus, rectum, and urethra. It is probable indeed that, in some instances at least, the narrowing of the part is rendered less rapid by this agency, and that in the stationary urethral strictures sometimes met with in elderly men it may arrest the stricturing process and prevent its becoming absolute. But the influence of liquid and pulaceous matters must be limited in causing dilatation by the fact that their chief energy is exerted on the walls of the viscus above the narrowest part of the stricture, where we find the dilatation that exists above all such narrowings. The moment the mass is propelled into the jaws of the stricture it experiences a diminution of pressure, owing to there being none below, and it escapes through without exercising more than a feeble influence on the narrowest part of the stenosis. Thus it fails to exercise any such pressure there as causes the local irritation, followed by moderate inflammation, softening, and yielding, which we believe to be the mechanism by which a bougie dilates. But since bougies are out of the question in non-operative treatment of the pylorus, it seemed probable that if solid spheres of the diameter of bougies suspended in the food were passed through the stenosis they might act like bougies and produce the same results. Whether the natural forces operating in propelling onwards the food would suffice to carry them through, and whether unforeseen difficulties might not arise, could be ascertained only by an actual trial. The first attempts were made with spheres of sugar coated with various substances which it was supposed would resist the digestive process until they had passed the pylorus; and several materials were made use of to form the spheres. But nothing was found suitable save gutta-percha rolled in the hand into globules, and these arranged into sizes by passing them through a gauge for urethral or œsophageal bougies. Gutta-percha spheres are easily and simply made, and, being of almost the specific gravity of the stomach contents, have no tendency to settle in the lowest part of the stomach or to float in the uppermost strata of its contents. The gauges chosen were those on the French scale, which gives a greater selection of sizes and a more gradual dilatation; but so sensitive is the pylorus that it was afterwards found convenient to mark intermediate sizes between two numbers, thus between, say, Nos. 20 and 21 would come 20+ and 21-, the former being one that passed with difficulty through No. 20 aperture, the latter passing with ease through No. 21 aperture of the gauge plate. It was at first thought that the spheres would be most efficacious if given by the mouth at night, the patient sleeping on his left side; but they were found to cause sleeplessness from restlessness of the lower extremities ("fidgets") and bad nightmares, so that this was abandoned, and they were given in the early morning, just after breakfast, and the patient allowed to go about his usual avocations. By this plan they caused less discomfort, and the only precaution taken was to forbid very hot food and liquids, which might have softened the gutta-percha so much as to destroy the rigidity of the sphere. They are found in the fæces, having passed through the alimentary tract without alteration. It is not difficult, by observation of the patient's symptoms, to form an approximate

idea of the size of the pylorus in cases of stricture. If the pylorus be narrowed at all this is at once shown by the discomfort or suffering that follows the eating of large morsels of tough food, such as beef and mutton. Moderate mastication does not reduce such morsels full of tough fibrous structures to such a size as to permit of their passing through the orifice without inconvenience, and the patient experiences uneasiness or prolonged cramp-like pains, extending from the right epigastric region to the angle of the left scapula, an hour or two after eating, and continuing until they are relieved by a gurgle of flatus and food passing into the duodenum. Hence such patients avoid these articles of food instinctively, and select softer substances, like fish, or more finely divided foods, like minced meat, puddings, and pulpy articles of diet. If ordinary minced meat can be taken without discomfort, the stricture is certainly greater in size than a No. 10 or No. 20 urethral bougie of the French scale. If the orifice is less in size than this, only liquid and pulpy foods, containing no solid particles larger than boiled rice, can be taken without distress.

These data are of assistance in commencing the treatment as by regarding them the approximate size of sphere to use can be pretty well ascertained. The treatment is best commenced by administering immediately after breakfast a sphere which is considerably less in size than the estimated size of the stricture, the patient swallowing it like a pill in a mouthful of some cold liquid. If it causes no feeling of uneasiness in the pyloric region a larger size should be given next morning, and so on. When the effective size has been reached it will be known by its causing within twelve hours uneasiness or soreness in the pyloric region, and perhaps cramp-like pains in the stomach, until it has traversed the stenosed portion of the bowel. These pains are very characteristic, and as the treatment has to be guided by their appearance and nature a more minute description of them may be useful. After a sphere which just fits the pyloric stricture has been swallowed, a certain time, varying from three quarters of an hour to five or six hours, or even more, elapses without any unusual sensation, and then discomfort gradually comes on in the pyloric region, in nature something between a stitch and a cramp, and often accompanied by intermittent cramp-like pains extending along the stomach towards the spleen or left scapular angle. The former sensations I presume to be caused by the sphere irritating the pylorus as it passes through the stricture, and where the stricture is a long one the discomfort can be felt passing along it as the sphere advances, and finally it disappears with a rush or two of flatus as the sphere escapes into the duodenum beyond; the latter intermittent cramp seems to be due to the efforts of the stomach to overcome the obstruction. The amount of discomfort experienced by the patient is in proportion to the tightness with which the sphere fits the stricture; should this not be excessive, a slight soreness at most may be felt on the following day, or even for a day or two, when food is passing the narrow part; but if it be excessive the pain may be sharp, knife-like, or, like the pain of ulceration, may be accompanied by tenderness on pressure over the pylorus, and may continue for a day or two, or even a week or more. In this case it is generally associated with heartburn and acidity, and is significant, I incline to believe, of small fissures or abrasions of the stricture having been caused, for the employment of alkalies and bismuth, to keep the contents of the stomach alkaline, is very serviceable in overcoming it. Such attacks occurring during the dilatation treatment demand care lest the size of the spheres be unduly increased before they have completely subsided, and until this takes place it is well to rest satisfied with maintaining the dilatation already obtained, and administer only spheres of the same dimensions, or even to use them a size smaller and allow it to retrograde somewhat. In the chart of a case that is given in this paper such a condition may be seen to have occurred and proved obstinate from the 120th to the 280th day of treatment.

After the size of the stricture has been determined the treatment consists in administering successively larger spheres at intervals of five days, or as nearly so as possible. If the sphere be of suitable size some uneasiness ought to be felt during its passage through the pylorus, and on this account it is advisable to administer it in the morning, for it is less annoying during the movement and occupations of the day than at night, when the discomfort is more observed, and gives rise to bad dreams, nightmares, insomnia, and sometimes nerve pains, resembling the pricking of a needle,

in the right lower extremity, or it may be in both lower limbs. Next day slight pyloric discomfort is usual after food, but is unimportant unless it become severe or prolonged, in which case the next sphere should be used of the same or a less size. The spheres produce no uneasiness in their passage along the rest of the intestinal tract. The accompanying chart exhibits the progress of cure in a case where the stenosis was due to inflammation and perihepatitis. It will be seen that the progress is very slow. I incline to think that it never can be otherwise in these cases if safety is to be ensured; but my experience is confined to four cases, of which that charted here was the only one satisfactorily observed. In it 810 days were required to dilate the stricture from sixteen to forty millimetres of circumference, as shown by the thin tracing, or from five up to fourteen millimetres diameter, as shown by the thick tracing. Sometimes, it will be observed, the dilatation made no progress for considerable periods, perhaps because great caution was observed. But on the whole the dilatation made steady progress, and the patient's condition and symptoms improved along with it. The dilatation has not been pushed beyond 40. French bougie scale, as with care in diet this is sufficient for the wants of the patient, and he suffers only when he eats unminced flesh. One of the other cases proved to be cancerous, and the treatment was given up. In the third case I could not learn the result, as the patient passed out of my hands; and in the fourth case the stricture was so small that only water, milk, and beef-tee could be taken, the stomach was dilated, and the patient died before it could be ascertained if even the smallest sphere had passed through. Operative measures were steadily declined in this case by the patient. No post-mortem examination was permitted, but I imagine the stricture was barely large enough to admit an ordinary probe. This shows that only where the treatment is early begun is there a good prospect of its succeeding. But in such cases, where the patient has the necessary intelligence and perseverance and the medical attendant can watch over, encourage, and direct him, I am satisfied that the results can surely be counted upon, and a perilous and doubtful operative procedure avoided. The method may possibly be employed with advantage in other strictures of the intestinal tract, but I have had no opportunity of employing it in any such.

Aberdeen.

A CASE OF CHOLECYSTENTEROSTOMY WITH THE USE OF MURPHY'S BUTTON.

By WILLIAM PAUL SWAIN, F.R.C.S. ENG.,

SURGEON TO THE SOUTH DEVON AND EAST CORNWALL HOSPITAL.

A SHORT time ago the notes of a case of successful enterectomy with the use of Murphy's button were published in THE LANCET.¹ I now record the history of a still more interesting case which has since been under my care. For want of a better term I have called the operation which I am about to describe "cholecystenterostomy," a fearful name indeed, and one which, after all, may not be applicable to the case in point. On Oct. 12th, 1894, I was asked by Dr. Clay to see a girl aged seventeen years, who had been brought to him for the first time on the preceding day. She had been ailing more or less for two years. In January, 1894, she became jaundiced, and a swelling formed under the liver. She had been treated by two medical men with mercury and other drugs: but in spite of their treatment the jaundice deepened and the swelling under the liver increased in size. They appear then to have told the parents that nothing more could be done, whereupon Dr. Clay was consulted. The condition of the patient when I saw her was briefly as follows. She was very deeply jaundiced; the urine was the colour of porter. The stools were white. She suffered no particular pain, had not been sick, and throughout her illness neither of these symptoms had been present. She was much emaciated. There was a large abdominal tumour reaching from below the liver to the brim of the pelvis and across the abdomen obliquely about three inches to the left of the umbilicus. The whole swelling was absolutely dull on percussion,

and the merest tap on any part of it produced a thrill of fluctuation. Taking the sum of her symptoms we had little doubt that it was a distended gall-bladder, although the possibility of a hydatid cyst was suggested. I aspirated the tumour with a full-sized aspirating needle, and we immediately perceived the characteristic fluid of distended gall-bladder. As if to make assurance doubly sure, towards the latter end of the aspiration a gall-stone struck the cannula repeatedly, and the click of impact was heard by Dr. Clay, the father, and myself. The quantity of fluid withdrawn was six pints and one ounce. No evil results followed the aspiration, and I did not see the patient again until Oct. 17th, when I found that the swelling was as large as ever. We then advised that an operation should be performed, and for this purpose she was removed to the private home for patients, and on the following day I operated on her. An incision about four inches long was made a little to the outer side of the right linea semilunaris. The integuments were very thinly spread over the tumour and the peritoneum was rapidly reached and opened. The cyst, being exposed and packed well round with small sponges, was tapped with an aspirating needle. Fluid of the same character as before was withdrawn, but to the amount of seven pints and twelve ounces. On passing the hand into the abdominal cavity the cyst was found to be firmly adherent to the intestine in all directions, the transverse colon being spread out over it. A small opening was now made sufficiently large to admit the forefinger. The cyst wall was very thin, but tough. Externally it was of a dark chocolate colour; the cut edge was rather white, and the interior bile-stained. On introducing the forefinger, after a prolonged search no gall-stone could be found, although, as previously stated, the presence of one could not be doubted. The finger passed upwards and inwards towards the liver into a passage with a crescentic opening, which I believed to be the common bile-duct; but a probe passed down far beyond the finger impinged on no stone. Up to this time I had no doubt but that I was dealing with a huge dilated gall-bladder; but my astonishment may be appreciated when I found, in the course of further investigation as to the relation of the parts outside the cyst, the gall-bladder in its normal position, somewhat pale in colour, undistended by bile, and containing no gall-stones. The question now arose as to what course was the best to pursue. To remove the cyst was impossible. To stitch it to the parietes seemed to condemn the patient to a perpetual fistula, or, at any rate, to very prolonged drainage. I decided, therefore, to accept the other alternative and to attach the cyst to the intestine. Without much trouble I succeeded in drawing up a good coil of jejunum close to the duodenum. My great difficulty was to get a good surface on the cyst. In order to do this I had to tear through the two layers of the mesocolon, and even then the surface obtained was limited. The cyst was then rapidly attached to the bowel by Murphy's button in the manner described by him.² The small original opening made to explore the cyst was closed with Lembert's sutures. The peritoneal cavity, which had been thoroughly well packed with sponges, was now cleansed and the pouch to the outer side and beneath the liver drained with a Keith's tube. The wound was closed with silk-worm gut sutures. On Oct. 19th the patient had no sickness. She had passed a good night. The temperature was 99° 2' F. Flatus was passed by the rectum. About three drachms of bloody fluid were drawn off from the drainage-tube. She was fed per rectum with beef-tee and brandy enemata. On the 20th the temperature in the morning was 100° 8', in the evening 99° 8'. Only two drachms of bloody fluid were drawn off from the drainage-tube. Small quantities of peptonised milk were given by the mouth. On the 21st the bowels were freely opened at 8 A.M., the evacuation being stained with bile. The urine was much less highly coloured. On the 23rd the bowels were again opened freely, soft pulsatious evacuations quite natural in colour resulting. The urine was less highly coloured. The jaundiced appearance was much less pronounced. On the 25th the stitches and the drainage-tube were removed. The bowels were open. From this date the record is somewhat monotonous. She was sufficiently well to be removed to her home on Nov. 20th. The jaundice has disappeared, the urine and evacuations being normal. No return of the distension has taken place. She has but one unfavourable symptom, and that is an occasional rise of temperature at night to 101° or 102°. Up to this time (Dec. 10th) the button has not appeared.

¹ THE LANCET, Oct. 20th, 1894.

² THE LANCET, Sept. 15th, 1894.

Remarks.—The question that arises is, What was the nature of the case? Up to the time of the operation, and even after it had been commenced and the cyst was opened, there was every reason to believe that it was a gall-bladder enormously distended. But the discovery of the gall-bladder in its normal situation and, if anything, less than its normal size put this idea at once out of the question. That it was a hydatid cyst pressing on the duct could not be entertained, as the fluid drawn off at the first aspiration had been carefully examined and no indications of hydatids had been found. Neither could I find any cancerous tumour of the pancreas or elsewhere which by occlusion of the duct might have produced the symptoms. I believed at the time that I had to deal with a distended duct. I have in vain searched all the records at my command and have found nothing quite resembling this case. In THE LANCET³ there is the record of a case of distended and sacculated common duct. The duct had ruptured, and the slit was plugged by a movable gall-stone. In the Reports of the Bristol Medico-Chirurgical Society⁴ there is a case more resembling the present one. It was that of a child four years of age who had suffered from recurrent attacks of jaundice, and for a year before death with an abdominal tumour in the region of the gall-bladder. Cholecystotomy was performed, and twenty-nine ounces of greenish fluid were removed. The patient died a week after the operation, and at the post-mortem examination it was found that the sac of the tumour was a greatly distended common bile-duct. There is one other explanation. Was it a case of double gall-bladder? That such a condition may exist is demonstrated by the report of a post-mortem examination of a girl aged eleven years in whom a double gall-bladder was found to exist.⁵ The non-appearance of the button may be accounted for by its falling back into the large cyst instead of being carried into the intestine. One can hardly think that it can be a source of danger if so situated. It seems to have done its work effectually and established a permanent opening between the cyst and the intestine.

Plymouth.

Clinical Notes: MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

AN EXTREME CASE OF ANGINA LUDOVICI ARISING FROM AN INFLAMED CARIOUS TOOTH; DEATH WHILE UNDER OPERATION.

BY A. E. PREST HUGHES, L.R.C.P. LOND.,
M.R.C.S. ENG.,

SENIOR RESIDENT MEDICAL OFFICER, UNION INFIRMARY, FIR VALE,
SHEFFIELD.

THE patient, aged thirty-one years, was brought to the Union Infirmary, Fir Vale, having for ten days previously complained of frequent attacks of pain due to a decayed tooth. Two days before admission a swelling under the jaw was noticed, which on the following day grew much larger and in the evening had extended to the front of the neck, and had forced his tongue up so much that he could hardly swallow or speak. When I saw him at the hospital lodge he was in a very distressed condition, only able to whisper and quite unable to swallow, the saliva dribbling from his mouth. The whole of the tissues on the front of the neck were immensely swollen, hard and brawny to the touch, and not pitting on pressure. There was no redness of the skin or signs of pus anywhere. The swelling extended from the angles of the jaw on each side forwards under the chin, and downwards over the front of the neck on to the thorax as far as the upper border of the third costal cartilages. The jaw was immovably fixed and the tongue forced up against the roof of his mouth. His respiration was greatly embarrassed, and the temperature was 103.5° F. He was at once put to bed, and I saw him half an hour later, when he appeared worse than on admission. He was sitting up in

bed breathing with much difficulty, and it was evident that he might be suffocated at any moment. Having explained matters to him and obtained his consent to an operation, chloroform was administered on a piece of flannel stretched over a metal frame. He passed under its influence without much struggling, only two drachms being required to render him unconscious. The inhaler was then removed, and I made an incision through the swollen tissues, commencing at the symphysis of the jaw, and carried it down the centre line of the neck as far as the lower border of the larynx. It was necessary to carry the incision to a depth of between an inch and a half and two inches to cut quite through the affected tissues. The parts were quite pale, very hard to cut, and no pus or discharge of any kind came from the wound. While making subsidiary incisions into the swelling on the wall of the thorax the patient's respiration became still more embarrassed, chest movements continuing, but no air entering the lungs, his face became cyanosed and the radial pulse became imperceptible. I at once opened the trachea, the operation being rendered difficult from the swollen state of the parts, and introduced a tube. Artificial respiration was begun, and all the ordinary methods of inducing respiration employed, including the passage of a catheter into the trachea through the wound and the inflation of the lungs through it, together with the injection of ether into the heart muscle, but the patient never made another attempt at breathing, although we persisted for nearly half an hour in our attempts to resuscitate him. Before commencing the operation we had discussed the advisability of performing a preliminary tracheotomy, but decided that incision of the swollen tissues would be sufficient to relieve him. At the inquest the jury returned a verdict of "Death from suffocation while undergoing an operation for cellulitis." No post-mortem examination was allowed.

Fir Vale, Sheffield.

TREATMENT OF BURNS.

BY S. GROSE, M.D. ST. AND., F.R.C.S. ENG.,
HON. MEDICAL OFFICER, MELKSHAM COTTAGE HOSPITAL.

LATELY it has fallen to my lot to treat certain severe burns, typical cases frequently met with when the clothes catch fire, in which extensive injuries to the third and fourth degrees are inflicted on the trunk and extremities. Lint soaked in warm carbolic carbolised oil with a thick envelope of cotton-wool is, perhaps, the best application for the first week; but the nauseous smell of the linseed oil, combined with the fetor of purulent discharge, is horribly offensive and helps to keep up the tendency to diarrhoea common at this period, which is frequently attributed to duodenal ulcer. Let me recommend the following alternative treatment. Dress the vast, beef-red, profusely suppurating wounds with gall ointment, thickly spread on strips of lint, or with ointment of galls and opium, or boric ointment having about a drachm of finely powdered galls to the ounce; wrap thickly in cotton-wool and bandage firmly, not loosely. Improvement is rapid, the smell diminishes, and the sufferer finds the treatment comforting. The admirable effect of gall ointment in coagulating albumen and restraining luxuriant granulations would seem to suggest it as a usual dressing in these cases; but none of our authorities mention it, nor have I seen it used excepting by myself. Indeed, the only mention of galls for treatment of burns that can be found in the "ever faithful, ever sure" Neale's Digest is an article written in 1852, claiming that ointment of galls prevents contraction of cicatrix. It is generally recommended that bandages in these cases should be lightly put on. But the fungous granulations are certainly more effectively restrained by firm pressure over elastic cotton-wool; and there can be no question that this treatment is more merciful than the application of nitrate of silver, whilst equally useful.

Melksham, Wilts.

A CASE OF SNAKE-BITE TREATED BY INJECTIONS OF STRYCHNINE; RECOVERY.

BY M. PERCEVAL, L.R.C.P. IREL.

AS the value of strychnine in cases of snake-bite is being much discussed at the present time, perhaps the following case may be of sufficient interest to publish in

³ THE LANCET, May 6th, 1882.

⁴ Bristol Medico-Chirurgical Journal, Jan. 10th, 1894.

⁵ THE LANCET, Dec. 4th, 1886.

THE LANCET. On Dec. 18th, 1894, a man was brought a distance of eighteen miles to my house at 4.30 A.M. suffering from snake-bite inflicted four hours previously. He was bitten when asleep, being aroused by the snake "chawing" at his lower lip, and on awakening he found a brown snake 2 ft. 6 in. long hanging from it, which he pulled off with his arm. On first being seen the patient was pale; the whole surface of the body was bathed in a cold perspiration, the pupils were widely dilated, the pulse was barely perceptible, rapid, irregular, and intermittent, and the breathing of a heavy sighing quality; characteristic marks of a bite were plainly seen on the lip. He was carried from the buggy, being unable to stand, was vomiting, and complained of extreme giddiness and as if about to die. I injected one-tenth of a grain of strychnine, repeating the injection twice at intervals of ten minutes. After the second injection marked improvement was evident in the pulse; after the third injection there was still further improvement of the pulse; the intermittency was gone, the rate was 96, and the breathing easier. He expressed himself as feeling better. Although the giddiness had improved he was not able to stand. I continued injections of one-fifteenth of a grain at intervals of twenty minutes with still greater improvement in the pulse and breathing; there was no further perspiration after the fourth injection. In an hour he was able to walk with support, but complained again of giddiness; the gait became staggering, and the pulse again almost imperceptible. These symptoms improved in a few minutes on his assuming the recumbent position. At the end of another half-hour I was able to admit him to hospital. During the day he only complained of drowsiness. At 6 P.M. he was attacked with vomiting and threw up a pint of fluid of a coffee-ground character. It has been pointed out that persons suffering from snake-bite are liable to hæmorrhage from mucous surfaces, but this is the first appearance of such in my experience, although I have now treated seven cases with strychnine, with recovery. On Dec. 19th and 20th he complained of stiffness of the jaws and nausea. He was discharged on the 24th well.

Isisford Hospital, Queensland, Australia.

PERFORATION OF APPENDIX CÆCI BY A PIN; GENERAL PERITONITIS, ENDING IN SUDDEN DEATH.

By PTOLEMY A. COLMER, M.R.C.S., L.R.C.P. LOND.,
MON. SURGEON, YEovil DISTRICT HOSPITAL AND DISPENSARY.

ON Oct. 3rd, 1894, about 7.45 A.M., I was called to see a boy seven and a half years of age. On my arrival at the house a few minutes after eight I was told the boy had died before the messenger could have reached my house. I examined the body, which was that of a well-nourished and apparently healthy lad, and nothing could be noted with the exception that the abdomen was a little distended. I obtained the following history from the mother. On Sept. 30th he appeared to be poorly, vomiting and complaining of pain in his abdomen, which she put down to be a bilious attack and administered a dose of castor-oil, which was repeated on the following day as the previous dose had taken no effect. On Oct. 2nd, the boy being no better, she went to a druggist, who prescribed a powder (one grain of calomel and six grains of sugar), which was immediately vomited, and in the evening, as this also took no effect, a second powder was given. On the following morning the boy appeared better, and took a cup of tea and milk about 7.30, immediately after which he wanted to have the use of his bowels. He was taken out of bed and placed on a chamber, when he passed a little fluid motion, after which, being replaced in bed (to use the woman's words), he seemed to alter and died in about four minutes. The following morning I made a necropsy on the coroner's order and found the following interesting condition. On opening the abdomen there were signs of recent general peritonitis, which were especially marked around the cæcum; the vermiform appendix was much thickened and enlarged, and presented a perforation through which was projecting a sharp point and within which could be felt a hard body. On opening the appendix after removal I found a body much resembling a date stone and apparently composed of hardened fecal matter, from one end of which was protruding a sharp point evidently that of a pin. The

other organs were natural with the exception of the bases of the lungs, which were congested. I may say there is no history to be got of the boy having swallowed a pin, although there is a history of his having swallowed a shot about last March.

VICTORIA HOSPITAL FOR CHILDREN.

ACUTE INTUSSUSCEPTION IN INFANTS.

(Under the care of Mr. T. P. PICK and Mr. H. F. WATERHOUSE.)

THESE cases form a contribution to the series of cases of intussusception to which we recently drew attention in the columns of THE LANCET. The first one is especially interesting, as it adds another to the small list of successes after operation for intussusception in children which Mr. Roughton has tabulated. We have before referred in THE LANCET to two other cases which were successfully subjected to operation and which are not included in the list named, cases under the care of Mr. Barrow and Mr. Berry respectively at the Royal Free Hospital. Mr. Pick in his remarks agrees with our expressions as to the treatment of intussusception, but emphasises the importance of disturbing the parts as little as possible. We fear that in a large number of the cases where patients are submitted to operation the consent of parents is obtained at such a late stage of the illness that adhesions are apt to prevent the surgeon reducing the condition by merely intra-abdominal manipulation, and in other cases the swelling of the intussusception acts as an insuperable obstacle to reduction unless the affected part is manipulated outside the abdomen. This swelling is sometimes present within a few hours after the onset of the intussusception. For the notes of these cases we are indebted to Mr. D. A. Chaning Pearce, house surgeon.

CASE 1.—A healthy, well-nourished infant, one year of age, was admitted into the Victoria Hospital for Children on the evening of Feb. 5th, 1895, under the care of Mr. T. Pickering Pick. The mother stated that for two days the infant had seemed poorly, had vomited three or four times, and had passed motions which were loose, but not frequent. About twenty hours before admission a little blood was noticed in the motion for the first time. Since then there had been no motion, and vomiting had only occurred once. An hour before admission a red mass was found protruding from the anus, but was easily pushed back by the mother. A good deal of blood was passed at the same time. On admission the child was found to be well nourished and not at all collapsed. The abdomen was not distended, and on palpation a distinct tumour could be felt without difficulty, extending along the whole course of the colon. Upon examination per rectum a mass could be felt in the rectum, extending down to the anus, which was quite unmovable. The child was at once placed under the influence of chloroform, and Mr. Pick proceeded to try reduction by manipulation through the abdominal wall, the pelvis being raised and the mass in the rectum pushed up as far as possible by the finger of an assistant. By this means the intussusception could be felt to be reduced as far as the splenic flexure of the colon, but beyond this reduction could not be accomplished. Inflation of air was next tried, but appeared to produce no result whatever and was therefore quickly abandoned. Warm water was now tried and the bowel filled under considerable pressure until the whole of the colon could be felt distended with the fluid. This was thought at first to have been successful as the mass disappeared from the rectum, but as soon as the water was

allowed to flow away the intussusception returned and could be felt per rectum and through the abdominal wall. It was believed now that nothing short of operative interference would be of any avail, and abdominal section was decided upon; and as the child seemed in spite of all these proceedings to be in a pretty fair state it was decided to proceed with the operation at once. A small incision was made in the middle line of the abdomen, below the umbilicus, of sufficient size to admit the finger and thumb. These digits were introduced into the peritoneal cavity, and the rectum was grasped at its upper part just below the intussusception; by a squeezing movement of the finger and thumb the mass was readily pushed back through the whole length of the colon and speedily reduced. The cæcum was now brought up to the external wound in order to make sure that the ileo-cæcal valve was quite clear; its coats were noticed to be thickened and infiltrated. At no period was any intestine allowed to escape from the abdominal cavity. The wound was sewn up and dressed and the infant sent back to its cot. The whole operation occupied from an hour to an hour and a half. The child was considerably collapsed for some hours, but took food (raw meat juice, with a few drops of brandy) readily and without any vomiting. It passed normal motions during the next twenty-four hours and its recovery was rapid and complete.

CASE 2.—A fat, rickety male infant aged nine months was admitted into the Victoria Hospital for Children on Feb. 11th, 1895, under the care of Mr. H. F. Waterhouse. The child had been given a "cooling powder" the night before and on the morning of admission much blood-stained mucus was found on the napkin. There had been no motion since and vomiting had occurred twice. Upon examination the rectum was found to be occupied by a large intussusception, which could also plainly be felt through the abdominal wall. An anæsthetic was at once given and the colon inflated with air. This was probably successful, as the intussusception disappeared from the rectum and could no longer be felt through the abdominal wall. In order, however, to make matters certain, Mr. Waterhouse filled the bowel with water at a moderate pressure, and as it was found to distend the colon readily as far as the ileo-cæcal valve it was concluded that the intussusception had been reduced. The child was therefore sent back to bed and made an uninterrupted recovery.

Remarks by Mr. PICK.—These two cases, which have occurred quite recently in the Victoria Hospital for Children, appear to me to be worthy of record in connexion with the very interesting case under the care of Mr. Roughton given in the Hospital Mirror of THE LANCET of Feb. 23rd. Mr. Roughton attributes the recovery after laparotomy in his case to the early performance of the operation without previous attempts at inflation or injection. These two cases seem to show—(1) that it is possible to cure some of these cases by simpler means than laparotomy, and (2) that in spite of prolonged attempts at reduction recovery may take place if abdominal section has eventually to be resorted to. With regard to the first point, it must be admitted by all surgeons who have much experience of these cases—and, indeed, Mr. Roughton admits it himself—that many cases of intussusception may be reduced by manipulation, by inflation, and by injection, especially when these remedies are applied early. I could from my own experience give records of several of these cases. Surely, then, it is better to try those measures which hold out a prospect of cure first before resorting to such a very formidable operation as abdominal section in an infant during the first twelve months of life. The amount of shock produced in these little infants is so considerable that the probabilities of a successful issue to a case of laparotomy are very slight, even if the operation is undertaken under the most favourable circumstances and at the earliest possible time, and when no previous attempts at reduction have been made. And even if these attempts have been made and have not been successful, the first case recorded seems to show that a successful result may be obtained. In my opinion a great point in connexion with the operation of abdominal section for intussusception in children is to take every care never to allow any of the intestine to escape from the abdominal wound. If it does there is always difficulty in getting it back, involving damage to the gut in the necessary manipulation. A small opening should be made in the abdominal wall, just sufficiently large to admit the finger and thumb. These should be immediately introduced and the intussusception sought for. When found the gut must be seized below the intussusception, and

by a gentle kneading and pushing movement the intussusception can generally readily be reduced without bringing it out of the abdominal cavity.

DERBYSHIRE ROYAL INFIRMARY.

A CASE OF ADVANCED MENINGITIS; CRANIOTOMY;
RECOVERY; REMARKS.

(Under the care of Dr. C. A. GREAVES.)

FOR the notes of this case we are indebted to Mr. C. H. Taylor, house surgeon, who remarks that the chief points of interest in the case are, firstly, that the symptoms were all those of tuberculous meningitis, and secondly, that the relief of intracranial pressure caused them all to subside. Whether this case was tuberculous or not, the suggestion naturally occurs, Should any cases of meningitis be allowed to die without the surgeon being called to give relief or to demonstrate that the cause is beyond his skill?

A girl aged thirteen years was admitted into the Derbyshire Royal Infirmary under the care of Dr. Greaves on Oct. 9th, 1894, with a medical man's certificate stating that she was suffering from enteric fever. The family history was doubtful as to tubercle. There had been no previous illnesses. The patient had always been a bright, intelligent girl, but during the previous few weeks had been quiet and subdued and difficult to rouse. She fell twice at school, but did not complain of any injury after the falls. Her parents attributed her "fainting attacks" to over-work. During the last week she had been ill in bed. On admission the patient was thin and emaciated, and her bones were very prominent. There was a hectic flush; the tongue was dry, and she lay with the head retracted, almost comatose. She could only swallow liquids with difficulty. The pupils were dilated, the right not reacting to light. There was double optic neuritis, most marked on the right side. Nothing was to be noted in the chest. The abdomen was retracted; *taches cérébrales* were present; there were no spots. The stools were natural in appearance. The temperature was 100° F.; the pulse 112, small and weak; and the respiration 32. During the next three weeks the notes show a persistently high temperature, 101° to 105° F., with occasional morning remissions, increasing emaciation and feebleness, increasing difficulty in taking nourishment, and a gradual lapsing into a condition of profound coma. After a consultation with Mr. Curgenvin it was decided, with the parents' consent, to open the cranial cavity on the right side to ascertain if the condition could be in any way relieved. On Oct. 30th, after the usual toilet preparations, a triangular flap of skin was dissected up behind the right ear. In doing this the mastoid vein communicating with the lateral sinus was cut across and required plugging, so dilated had it become from backward pressure. A small trephine was applied just above the level of the lateral sinus, exposing the dura mater, and on incising the latter a very large quantity of clear fluid escaped. A finger was then inserted, but beyond ascertaining that the brain had been pushed over towards the middle line nothing abnormal could be made out. The opening was then enlarged in the direction of the mastoid vein in order to better control the bleeding from it, but in doing so the lateral sinus was wounded and required plugging. As the hæmorrhage had been pretty considerable nothing further was done, and the patient was promptly put back to bed. For the next five days the oozing of cerebral fluid though the plugs was considerable, and the temperature still kept up slightly. The plugs were removed on the fifth day, and during the next few days the patient became slightly conscious and took nourishment better. During the next three weeks she gradually regained strength and consciousness, interrupted by three attacks of severe headache accompanied by fever, relieved by passing dressing forceps up through the wound into the cranial cavity, so as to allow some fluid to escape. The wound had healed completely by Dec. 27th. The patient has now (Jan. 1st) regained all her brightness and intelligence, and is physically a picture of health.

SUPERANNUATION ALLOWANCE.—Mr. William Hall, M.R.C.S., lately medical officer for the Tottenham district of the Edmonton Union, has been granted a superannuation allowance of £100 per annum.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

The Immunisation of Horses.—Adjourned Debate upon the Pathology of Diphtheria.

An ordinary meeting of this society was held on March 19th, the President, Dr. PAVY, being in the chair.

Mr. W. ROBERTSON read a paper on the Immunisation of Horses. He described the methods employed in the immunisation of horses for the preparation of diphtheria antitoxin, and the process of bleeding the animals when immune. He mentioned that suitable horses of the heavy draught class could be purchased for sums varying from £3 to £7. On purchase the horse is isolated and tested, generally twice, with mallein and then with tuberculin. If satisfactory, the animal is placed with the others. The injections are usually practised in front of the shoulder, due precautions being taken to ensure the sterilisation of the syringe &c. employed and of the skin over the site of puncture. It is seldom that the horse exhibits any uneasiness during the operation. Very small quantities of the toxine are used at first, usually not exceeding 1 c.c. The admixture of Gram's solution of iodine was soon discontinued as it was found to act as an irritant. The local lesion following the first inoculation is as a rule well marked. It presents itself as a diffuse soft swelling slightly painful on pressure, which reaches its greatest size in from six to seven hours, and persists for two or three days. The temperature follows the same course, falling to normal coincidentally with the disappearance of the local lesion. When this has taken place the inoculation is repeated, being raised by degrees, if the local and general effects are slight, until in seven weeks the dose has reached 50 c.c. This dose is given three times a week for a fortnight, and if no reaction is produced the dose is raised to 100 c.c. three times a week also for a fortnight, and then 200 c.c. for the same length of time at the same intervals. The period of time allowed to elapse varies in different animals, no inoculations being practised until the local swelling and the temperature have returned to normal. He observed that no two horses are alike in their power of resistance to the action of the toxine, and the disappearance of the local lesion and the fall of the temperature are also very variable. He has never known a horse to refuse its food after inoculation even when the temperature was very high and distinct rigors have occurred. Local necrosis of tissue was noted only four times out of many hundred inoculations. When thought to be sufficiently immune the horse is allowed a clear week's rest before being bled. The jugular vein is sought for, raised by pressure with the fingers, and an incision half an inch in length made through the skin and panniculus carnosus. The cannula is no longer inserted directly into the vein, but having been uncovered it is connected to Kitasato's flask by a piece of quarter-inch rubber tubing, and the cannula is then carefully inserted, avoiding introducing it into the sheath. When the flask is filled it can be replaced by merely pinching the rubber tube. The amount of blood that can be removed varies with the size of the animal, the average quantity being ten litres, though much more has been taken with impunity. The reason for not drawing off more is that if more than ten litres are withdrawn the last four or five litres do not clot properly, and the serum which separates is of a pink colour. The cannula is then withdrawn, pressing on the vein with the finger, and the wound is sponged with a 1 in 20 carbolic acid solution, the edges of the wound being fastened with two catgut sutures, dusted with iodoform and dressed with sterilised cotton-wool dipped in collodion. There has never been any difficulty in stopping the bleeding, and the vein has not once been obliterated. The flasks employed are conical in shape, being the ordinary two-litre and four-litre filtering flasks fitted with a rubber cork and two pieces of glass tubing, one of wide calibre to allow escape of air, the other of narrower dimensions, over the orifice of which is slipped the rubber tubing connected to the cannula. The tubes and flasks are duly sterilised in the steamer. After clotting of the blood the filled flasks are placed in a cool cellar, and in twenty-four hours a large amount of serum will have separated. The branch tube of the flask is then flamed in a spirit lamp, the wool plug removed, and the serum poured off into sterilised Winchester, the branch tube being replugged. The

amount of serum obtainable from the same quantity of blood varies greatly, the average yield being 50 per cent.

Dr. WASHBOURN, continuing the adjourned debate upon the Pathology of Diphtheria, said that Dr. Hunt's observations confirmed those of Roux with reference to the free access of oxygen favouring the production of serum. Dr. Hunt apparently considered the alkalinity of the cultivation to be the essential factor, the oxygen merely preventing the formation of acid; but additional facts were required before this view could be accepted. The rapid decline of toxicity in the cultivations after fourteen days was, he said, an important practical point, and he asked for further details in this respect. In reference to the dying out of the cultivations in nine days under free access of oxygen when methylene blue was used, he suggested that this substance acted deleteriously upon the cultivation in other ways than by simply carrying oxygen. He commented on the statement that a cultivation which yielded a powerful toxine did not necessarily contain bacilli of great virulence, and asked for further explanations. It must be clearly understood that the toxine is a specific proteid poison, but it was not necessarily the proteid which was the poison, but only its disposition and its active and specific quality. He thought that in discussing this matter Dr. Hunt had exceeded the boundaries of pathology. He discussed the alleged non-formation of tetanus antitoxin in fowls, and suggested that Dr. Hunt's failure to obtain a diphtheria antitoxin after injection of toxine was due to the period at which the blood was withdrawn not being suitable. He thought that the excretion of the toxine in the urine when given in large doses might account for the scanty production of antitoxin, and he pointed out that the antitoxic power of the blood was not sensibly diminished after removal of a quantity of blood equal to that contained in the whole body. He asked for further evidence of the view that this was due to a store of toxine present in the various organs. After stating his views in reference to the specific nature of antitoxin, he discussed the difference between infection with the living bacilli and with their toxines, adding that he considered the experiments in this respect somewhat unsatisfactory. He urged that an animal could not be said to be immune simply because it survived an inoculation, real immunity meaning that the animal suffered neither local nor constitutional effects after inoculation. He alluded to the presence of living bacilli in the throat of patients long after the symptoms had subsided, and raised the question whether the bacilli were still secreting toxines, and if so, whether their effects were being annulled *pari passu*. He mentioned in reference to bacterial associations that Dr. Goodall and he himself had failed to discover any relationship between such association and the severity of the case, though the presence of the streptococcus certainly appeared to explain certain complications. The majority of the so-called septic cases of diphtheria were, he thought, due to direct poisoning with diphtheria toxines, and he inclined to the view that the influence of associated streptococci had been much exaggerated. He concluded by stating in reference to the varieties of diphtheria bacilli that the short variety, which rarely produced a fatal effect in guinea-pigs, was the most usual form of the pseudo-diphtheria bacillus.—Dr. G. SIMS WOODHEAD said he had been struck by the differences in the quantity and activity of the poisons produced by the diphtheria bacillus in different broth cultures, even when the same culture was used. He had tried different methods of growing the bacillus to see the conditions in which the toxines were produced. He first used Roux's method, which yielded fairly virulent toxine directly from the membranes, the bacillus being of the long variety. When sown in flasks containing a much larger quantity of fluid kept constantly agitated they found that, although the virulence of the growth was not interfered with, the bacilli still living at the end of a month, the amount of toxine was small. When however, much thinner layers of fluid were used, as in Aronson's method, there was not only an increase in the growth of the organisms, but in the amount of toxine formed. It appeared therefore that there were two distinct sets of conditions: first, an increased supply of oxygen to the bacilli themselves, and, secondly, the action of a considerable quantity of oxygen on the production of the bacilli. If the action of the oxygen could be limited to the bacilli themselves without acting on the toxines they would have the best conditions possible. He pointed out that the poison formation of the bacilli might be quite distinct from their virulence, and it did not follow that if the bacillus did not live very well in the

tissues, that therefore it would not form large quantities of the poison. In regard to the alkalinity of the cultures he pointed out that it was not merely the alkalinity, as was proved by the fact that alkalinity obtained by the addition of soda solution did not give as good results as that resulting by oxygen. There was evidently something special in this alkaline quality. Moreover, keeping the solution alkaline did not increase the capacity of the organism for producing toxins, although they appeared very rapidly after the alkaline stage, or rather after the acid stage was past. He observed that it was the universal experience that great differences obtained in the resistance of different animals to toxins. He presumed that an animal which withstood the largest amount of toxin must take a longer time to give antitoxin, and that was his experience. He recalled the experiments with tetanus toxin, showing that if the relative immunity of a given animal were overcome by large doses of toxin a much better serum was obtained than was the case from a comparatively susceptible animal, a fact which held good in regard to the immunisation of the horse with diphtheria toxin. This was evidently a much more complicated matter than had at first been suspected. Roux and Viard, although maintaining that the action of the toxin was distinctly through the cells in the production of antitoxin serum, found that this action was very rapid, for by injecting toxin into a small animal, and then taking the blood from the ear, one could obtain a certain amount of antitoxin at once. Either the action must be spread out over a large number of cells or there must be some action directly on the serum. He agreed that it was better to give smaller quantities of toxin at shorter intervals after the first few inoculations, and he was making experiments in that direction. He mentioned that out of fifty post-mortem examinations of diphtheria patients in only five instances had he discovered the diphtheria bacillus in the lungs. In a large number of cases he had found micrococci in the pneumonic patches, and in only four had tracheotomy been performed. He admitted that it was almost impossible from the examination of a few tubes to say what organisms were present in a given case of diphtheria. In about 5 per cent. of the cases the bacillus was not found in the first cultures though present in abundance in the second, or it might be identified in the first culture, absent in the second, and present again in the third. The presumption was that with every care they must have been overlooked. He suggested that by-and-by, when physicians compared the clinical features of their cases with the bacteriological reports, given, for the most part, in ignorance of the nature of the case, much valuable information would be forthcoming. He believed mallein to be absolutely reliable, but he pointed out that it was the progressiveness of the swelling, along with a rise of temperature, that made the diagnosis reliable, not the mere swelling. Post-mortem examination had confirmed the mallein diagnosis in several cases in which glands were positively denied by the veterinary surgeon. Tuberculin was perhaps not quite so reliable, but if properly used it was also a valuable test. In conclusion he pointed out that the diphtheria bacillus was a far more protean organism than was thought. He had seen wedged shape, pointed, long, short, and divided club shape—in fact, a very large number of forms of this same bacillus. He said the short form was met with most commonly in convalescing patients.—Mr. LENNOX BROWNE showed two specimens of the so-called pseudo-bacillus of diphtheria: the first from a child who recovered under one dose of antitoxin serum; the second from a male patient aged twenty-five, whose symptoms recovered those of lacunar tonsillitis rather than diphtheria, though bacteriological examination revealed the presence of the Klebs-Löffler bacillus of the long variety in an almost pure culture. He made a good recovery without paralysis. Three months later this patient's tonsils were removed, and two days later the wound was seen to be partially covered with patches of pearly-grey exudate, which on removal exposed a freely bleeding surface. A culture from the exudate on blood serum showed sparse colonies of segmental bacilli of the short variety. A subculture showed colonies still more sparse, consisting mainly of cocci; and a further subculture failed to produce any bacilli, the whole growth consisting of cocci. Eleven days later, though the wound had healed, a culture from the surface yielded an almost pure growth of staphylococcus aureus. He remarked that the term "pseudo-bacillus" was a most unfortunate one, for these specimens being typical of what was usually found in similar circumstances proved

that they were true bacilli which were undergoing a process of attenuation in development and virulence. He also protested against any importance being attached to the presence of the "Brisou" coccus, this being an organism frequently found in the secretions of the oral and respiratory passages quite irrespectively of diphtheria and absolutely without either diagnostic or prognostic significance.—Mr. BOKENHAM said he had observed that the antitoxin prepared by Klein's method protected the animals inoculated with it against both the diphtheria bacilli and their toxins.—Dr. HUNT, in reply, said he had found that diphtheria cultures cultivated on thin layers of media which had air passed over them were living and well after the lapse of a month. Those bacilli which had been cultivated in a larger bulk of fluid through which air had been bubbled showed much less vitality at the end of a month. This seemed to show that if the bacilli were allowed to take their own air as they required it the products formed were more virulent. He thought there was a great future before the inquiry into the increased natural resistance of animals when they were treated with foreign proteids. He had examined fifty-eight specimens of diphtheric membrane, and in fifty-six of them the bacillus was virulent; he had never found a pseudo-bacillus. The action of associated streptococci was to increase the virulence of diphtheria bacilli, while when associated with staphylococci cases of diphtheria ran a milder course.—Mr. W. ROBERTSON, in reply, said that mallein was very reliable as a test for glands: if it gave a positive result it was certain that the animal had glands; if it gave a negative result it was not so certain that the animal had not glands. He had had no personal experience of the use of tuberculin in tuberculosis of horses, but in cattle, if tuberculin was properly used, the test was a reliable one.

OPHTHALMOLOGICAL SOCIETY.

Double Optic Atrophy with Peculiar Visual Fields.—Filaria Loa.—Traumatic Cataract with a Foreign Body embedded in the Lens.—A Form of Iritis not usually recognised.—Exhibition of Cases and Specimens.

AN ordinary meeting of this society was held on March 14th, the President, Dr. ARGYLL ROBERTSON, F.R.S.E., being in the chair.

Dr. GEORGE OGILVIE read notes of a case of Double Optic Atrophy with Peculiar Visual Fields. The patient was a man aged fifty-seven, who was a sorter of cigars and a moderate smoker. His vision failed in December, 1893. He had formerly had epileptic fits and came of a family with a very neurotic history. The movements of the eyes were normal; the pupils acted sluggishly to light. In October, 1894, the vision of the right eye was $\frac{1}{2}$, and of the left fingers at ten feet, with eccentric fixation. Mixed astigmatism was present in both eyes. He had floating opacities in the vitreous. Both optic discs were pale, and the retinal veins were tortuous; there was a congenital crescent in both eyes. The right visual field was contracted for white and colours. There was contraction of the left visual field and complete inferior hemianopia. There was neither sugar nor albumen in the urine; and no history of syphilis or alcohol. His knee-jerks were exaggerated; some ankle clonus was present. The character of the visual fields pointed to change in the optic nerve itself; it was a question if it were a primary atrophy or the result of a neuritis. From an old Moorfields Hospital letter in his possession it was found that he had attended there for optic neuritis. In February, 1895, the upper and inner quadrant of his right visual field was missing, giving an appearance of right lateral hemianopia.—Dr. JAMES TAYLOR referred to the history of past optic neuritis as being a sufficient explanation of the changes observed in the fundus. He thought it was unnecessary to assume any lesion in the occipital lobes, but he asked whether the vitreous opacities present in this case were not pathognomonic of syphilis.—Dr. A. BROWNE asked if there were any possibility of the existence of lead poisoning.

The PRESIDENT communicated further notes of a case of Filaria Loa which he had brought before the society in October last. After removal of the parasite the patient was not troubled again for six weeks; on Feb. 6th the worm was felt and seen again, and was sought for in vain. Two days later a swelling appeared in the right temporal region. On Feb. 13th the worm was felt beneath the right upper eyelid;

it wriggled across and then remained coiled up there. An incision was made, and after some dissection a fine filamentous body, smaller than the ordinary filaria, was found; this was identified later as part of the expressed oviduct; a well-formed filaria was found deeper in the tissues, with its oviduct protruding. The blood had been examined many times in the last six months, but no traces of the filaria or its embryos could be found. The patient had occasional swellings of the skin of the arm, such as often occurred among residents in Old Calabar. As to the origin of the worms in this case, although the patient had been careful about her drinking water, for ten days before leaving Old Calabar she had been too ill to purify the water, and she might have become infected by impure water then.

Dr. W. SPENCER WATSON described a case of Traumatic Cataract with a Foreign Body embedded in the Lens. The patient, a man aged twenty-nine, had several injuries of the right eye, but only accidentally discovered that the sight was affected some time after the more serious injury. He was not aware that a foreign body had entered his eye. The foreign body was seen, however, in the cataract, which was dealt with first by dissection, and subsequently by linear extraction, the foreign body being removed at the second of these operations. Everything went smoothly, and when the patient was seen a year later there was a normal-looking pupil, and vision remained good. Mr. Watson pointed out that the time for extraction when a foreign body was present required very careful regulation, the gradual softening of the lens being watched until it became of a gruelly consistence, and the operation performed before it had become fluid.—Dr. DRAKE BROCKMAN referred to the case of a Hindoo target-keeper who received a splinter of lead from a bullet in the left eye. There was a wound of the cornea, the lens was opaque, and embedded in it was a small piece of lead, fixing down the iris and projecting into the anterior chamber. The portion of iris transfixed was removed with the lens, and the eye recovered good vision with the aid of a convex glass.—Mr. MARSHALL related a somewhat similar case.—In reply to Mr. JOHNSON TAYLOR, Mr. SPENCER WATSON said the exact nature of the foreign body was not ascertained.

Mr. W. A. BRAILEY described a peculiar Form of Iritis not usually recognised. After a summary of cases he arrived at the following conclusions:—That a late Iritis sometimes follows an acquired syphilis, and that the average time of its attack does not vary much from thirteen years from the primary sore. That such Iritis is generally double-sided and its usual form an Iritis serosa—that is to say, an Iritis, or rather an Irido-cyclitis, with comparatively little tendency to the formation of posterior synechia, and accompanied by dots on the posterior corneal surfaces and also by a tendency to secondary glaucoma. That the patient may show other late manifestations of syphilis, as in the cases shown, of which one has ozena and the other choroiditis disseminata. That a similar late Iritis may follow an inherited syphilis, and that the average age of the subject of it, though varying within wide limits, approximates to twenty-one. That in inherited, as in acquired, syphilis the usual form is a double serous Iritis. The Iritis may, however, be of a much severer type, with varying tension and with the occlusion of the pupillary area with a layer of lymph, such lymph being, however, comparatively free from the iris at the pupillary edge. That such an Iritis may also be accompanied by larger and more cloudy dots on the posterior surface of or perhaps deep in the cornea, such deposits with the others resulting in the formation of a dense non-vascularising triangular plaque deep in or behind the lower part of the cornea. That the Iritis may more rarely be of a different type, either the gummatous with occasionally peripheral anterior synechia, or the adhesive, leading even to occlusion of the pupil and consequent secondary glaucoma. That apart from the Iritis which simply attends and is quite secondary in degree to severe interstitial keratitis, the late serous Iritis of inherited syphilis may show a close relation to interstitial keratitis. Thus a slight interstitial keratitis may be followed after a distinct interval by a gummatous Iritis, while the Iritis with blocked pupil, deep triangular corneal plaque, and varying tension may be accompanied by fine filmy or denser and more widely spread opacities in other parts of the cornea. Notched teeth are rare, or perhaps even uniformly wanting, in the pure Iritis serosa of late inherited syphilis, while they are present in increasing frequency as the disease approximates in its associated characters to interstitial keratitis. It is very noticeable that the subjects of the late serous Iritis of inherited syphilis

are often of extremely good physical development.—Mr. HIGGINS was of opinion that one of Mr. Brailey's cases appeared very like an old case of interstitial keratitis, and inquired whether such an intercurrent attack could have occurred.—Mr. SPENCER WATSON wished Mr. Brailey to point out the novel features in these cases; they had been familiar to him, and he believed they were generally recognised.—Mr. JESSOP referred to the presence of punctate dots on the anterior surface of the iris in one of the patients, which resembled those present in a case he had recently brought before the society.—Mr. LANG said that in one case there existed a ring synechia between the periphery of the iris and the cornea, which must impede filtration; others presented isolated anterior synechia.—Dr. HERN inquired whether the Iritis was primary or an extension from keratitis.—Mr. BRAILEY said the Iritis was independent of keratitis. The boy to whom Mr. Higgins referred had been continuously under observation, and the white plaque present had been seen to develop from a keratitis punctata, and not from interstitial keratitis.

The following cases and card specimens were shown:—

Dr. SYDNEY STEPHENSON: An Improved Test Type.

Dr. A. BRONNER: Wire Eye Shields for use after Cataract Operations.

Messrs. HARTRIDGE and GRIFFITH: Cholesteroline in Sub-retinal Fluid of a Detached Retina in the Eye of a child removed for Buphthalmos.

Mr. HARTRIDGE: Cholesteroline in the Anterior Chamber.

Mr. C. DEVEREUX MARSHALL: Microscopical Sections of (1) an Unusual Syphilitic Growth, and (2) Tuberculous Growth.

Mr. JESSOP: Primary Sore on Upper and Lower Lid.

Mr. VERNON: Case of Pulsating Tumour of Orbit.

BRITISH GYNÆCOLOGICAL SOCIETY.

Exhibition of Specimens.—The Dangers of Morphia in Gynecological Practice.—Leakage of an Ovarian Cyst in a girl aged thirteen.

A MEETING of this society was held on March 14th, Dr. CLEMENT GODSON, President, being in the chair.

Mr. F. BOWREMAN JESSETT showed a specimen representing a Cast of the Entire Uterus, which he had removed by packing the cavity of the uterus with chloride of zinc paste. The patient, aged forty-eight, had had an offensive discharge with pain and loss of flesh for seven months. The uterus was found fixed; the cervix was the seat of advanced ulcerated epithelioma. After scraping away as much of the growth as possible with the dredger, the paste was packed into the cavity of the uterus in the way previously described. Three weeks later the whole uterus came away as a slough. For a time there was a vesico-vaginal fistula. Four months after the operation there was no trace of malignant disease.—The PRESIDENT had seen many cases of this kind formerly at St. Bartholomew's Hospital, when they were regarded as hopeless and beyond relief.—Dr. PURCELL remarked that the surrounding structures in these cases escaped injury in a way one would not expect. He had not been able to tell in his own cases whether the peritoneal covering came away with the rest. The patients had, so far, done well.—Dr. ROUTH said he had used not only the chloride of zinc, but also strong nitric acid, the acid nitrate of mercury, and bromine. From the last, in a 20 per cent. solution, he had had very good results.—Mr. JESSETT replied. He said the pathologist had carefully examined the specimen to find the peritoneum, but thought it was not possible to state whether it was present or not. Twenty cases had been done at the hospital, happily without fatality, so no post-mortem examination had been made. He then gave some further details of the operation and promised to bring the later results before the society.

Dr. MACNAUGHTON JONES read the following paper upon the Dangers of Morphia in Gynecological Practice. He said: "I propose to consider the question of morphia administration in women from the following points of view: the influence of temperament on its action and effects; our knowledge of its physiological and psychological influences; and the precautions to be observed in its exhibition. With regard to temperament, I must ask your attention for a few minutes to that large class of sufferers from affections of the female generative organs commonly spoken of as 'nervous.'

The neurotic woman, I take it, is to be regarded in the light of a by-product of that unstable nervous organisation which we style the 'nervous temperament.' Such a temperament is frequently satisfied with little sleep. Under the influence of excitement fatigue is quickly recovered from, and a latent reserve force of energy appears ever ready on demand to carry its possessor over insurmountable obstacles. All this accumulated governmental control of will and nerve energy are missing in the neurotic, but none the less is that loss felt when the unequal struggle occurs between the sovereignty of an enfeebled, indeterminate will and the rebellious and more masterful emissaries—the woman's 'lower passions and lower pains.' While in health such individuals can pass through great physical and mental exertion without stimulants, but when the natural call on their reserve energy finds no response they apply the artificial spur of alcohol or some other excitant, such as morphia, to the flagging nerve cells. Such women are quite cognisant of the abeyance of the power to exercise free will. The desire to suppress the expression of pain is present, but the usual control is lost. Also, there is general hyperæsthesia of the peripheral nerves, which find in the frequently ill-nourished central cells a susceptibility to slight impulses and morbid sensitiveness with an exaggerated perception of any comparatively trifling stimulation. Here we are dealing with an *acquired* neurosis, for which possibly we may find no clue through atavistic transmission. On the other hand, we can frequently see in early childhood the traits of temperament which clearly foretell the future neurotic woman. Capriciousness, irritability, selfishness, restlessness, and excitability are the characteristics which stamp the moral prototype in the child of the adult neurasthenic and hysterical woman, though it is after puberty that we frequently find such distinctive features of character develop themselves. When a woman of this type marries, in the demands on her nervous system, if she be not sterile, which the claims of children and domestic duties involve her in, she generally escapes those neurotic and hysterical manifestations that are found in the unmarried and sterile. In the single woman of the 'neurotic' type we are more likely to meet with those erotic thoughts, desires, and practices that still further enervate her nervous system and enfeeble her central control. She is perhaps most of all the back drawing-room or boudoir woman who is apt to fall, to use Professor Clifford Allbutt's expression, 'into the net of the gynæcologist.' Turn we now for a moment to the *lymphatic* antithesis of this unfortunate victim to unbridled and morbid nervous and sexual impulses. There is a type of woman familiar to us all—indolent, lethargic, fanciful of ailments, with a superficiality bordering on childishness in conversation, dull of comprehension, readily open to flattery, even to her own self a bore, and often one to her husband and children if she be married. She is often found fringed with layers of pectoral and abdominal fat, the easy prey to quack systems of dieting and to the 'man of the world' physician. Her defective metabolism, added to a sexual voluptuousness, makes this proprietary article the registered dual property of the 'pure specialist' for gout, on the one hand, and the cotton-wool gynæcologist, on the other. She is one of the principal sources of revenue to the new *franc-tireurs* of the outposts of medicine—the ubiquitous masseurs or masseuses. With her every twinge is 'agonising,' to walk is impossible, and once let her evolve 'uterus and ovary' on the brain, and whether these organs be diseased or not they are made responsible for every ill her peccant flesh is heir to, not even excluding 'housemaid's knee.' She is not of the classical neurotic type previously described, though her visceral neuroses may in time come to be legion. She may suffer from congestive dysmenorrhœa and ovaralgia, her uterus may be as flabby as her brain, and her ovary be as fertile in aches as her imagination is in fanciful illusions. Her voluptuousness is not limited to her appetites of palate, and it is not infrequently manifested in various sexual abuses. She fancies she sleeps for many hours less than she actually does, and hence is often seeking for some new, when she has already exhausted every conceivable variety of reputed, hypnotic. While we find in the unmarried more frequently examples of the first type of temperament, married women furnish a larger proportion of the latter. Both, however, are to be found constantly as representatives of the habit of morphinism. Let us consider now the facts which are fully established regarding

the etiology and course of morphinism, leading up to the morphinomania. It is a curious fact that not until 1864, when Nusbaum¹ drew attention to the consequences following the abuse of injections of morphia, was there any serious notice taken of its ill-effects. The first English physician who seems to have written on the subject was Professor Clifford Allbutt, who drew attention in the *Practitioner* of 1870 to the dangers following incessant injections of morphia. [Dr. Macnaughton Jones here gave an exhaustive bibliography of morphinism.] It is important to note that so far as statistics appear to prove men are more subject than women to the morphia craving. Also the prevalence of morphinomania amongst medical men, nurses, and pharmacists has to be remembered, medical men representing by far the largest number of all classes in which the craving has been recorded. Out of 150 morphinomanacs noted by Lewinstein and Burkart 86 were either medical men or persons connected with the medical profession. Rochard considers that medical practitioners furnish more than half the number of male sufferers. Some of the most inveterate morphinists I have known have been medical men. One committed deliberate suicide by throwing himself from a window. This unfortunate prevalence of the propensity in the ranks of medicine may be accounted for, says Regnier, first, by the facility with which the drug is procured, and secondly by the arduous nature of a calling which oftentimes makes irresistible demands on a frame already over-fatigued and suffering. So far as the influence of age is concerned, it would appear that the majority of morphinomanacs will be found between the ages of twenty-one and fifty. [Dr. Macnaughton Jones then described graphically the downward course of the morphinomaniac.] What touches us here more especially is the influence exerted on the catamenial function through the morphia habit—namely, frequent arrest of the catamenia and constant irregularity or complete suppression. Sterility is at times the consequence of this arrest of uterine function. There is also to be remembered the undoubted effect of morphia on the embryo, and the fact that the infants of morphia-takers suffer immediately after birth from the consequences of the habit has to be recollected. But the fact before all others that I am anxious to emphasise, which has been clearly proved by a number of observers, is that what we understand by hysteria occupies the foremost place in the causation of morphinomania. Hysteria, neurasthenia, neuralgia, and cephalalgia are the correlated conditions often associated with sexual disturbances which stand in the forefront in the etiology of morphia abuse in women. And they are, unfortunately, the very conditions for which it is most frequently prescribed. Recall now the temperaments that I have endeavoured to depict as types of those most susceptible to the deleterious effects of morphia. They are distinctly those which all experience has proved are most likely to be conquered by the physiological action of the drug. Such persons are always importunate for its employment once they have experienced its effects, and the weak-kneed physician is compelled to yield to their importunity. A prescription is given, possibly a nurse is entrusted with the administration, and very frequently, when the nurse leaves, the patient retaining the prescription, not alone administers, but practically prescribes the medicament for herself. I have known a supply of a morphia solution of the British Pharmacopœia obtained daily at different druggists, and thus as much as eighteen or twenty grains of morphia have been taken subcutaneously within the twenty-four hours. The original prescription was copied at different establishments, and no demur was made to compounding it even after the lapse of two years from the date of the original prescription, nor was the physician who prescribed it made cognisant of the fact that it was so repeated. I cannot but look upon such a practice as a grave and dangerous abuse of that mutual trust which should exist between the physician and the pharmacist. When morphia can be readily obtained in large quantities the tendency often arises for one woman to recommend its use to another and even to go so far as to subcutaneously inject it into her friends. Thus the habit becomes contagious, and there is even a morbid delight felt in the act of puncturing, not alone herself, but others (Regnier). One other point I will only make a passing allusion to, and that is the double-edged nature of this weapon, when used

¹ Die Gefahren der subcutanen Injectionen. Bairisches Aerztisches Intelligenz Blatt.

by the surgeon after abdominal operations, in masking symptoms of peritonitis and possible interference with the natural process of cure through arrest of the secretions. As Greig Smith well says: 'The routine employment of morphia is to be condemned. Complications are better met with a system unimpregnated with morphia.' The moral of this paper is that there is a responsibility attached to the employment of morphia for the relief of pain in the affections of women not sufficiently recognised in practice. This responsibility imposes on the physician the duty of differentiating those cases in which morphia may almost be given with immunity from its toxic effects from those in which the risk of the intoxication by its repeated use is great. It is not too much to say that under no circumstances whatever should a patient be permitted to inject it herself, and it is questionable for many reasons whether relatives or friends, save under very exceptional circumstances, should accept the responsibility of doing so."—Dr. DUDLEY BUXTON thought Dr. Macnaughton Jones had done well to bring this subject before the society and thus emphasise the therapeutic as distinguished from the operative side of gynaecology. He had seen much of the bad effects of indiscriminate prescribing of morphia, and thought additional safeguards were required. He went further than the lecturer, and was of opinion that no druggist should dispense any poison a second time from one prescription unless initiated each time by the prescriber; nor should a medical man delegate to any other hands the hypodermic administration of such a potent drug as morphia.—Dr. CHAPMAN GRIGG said that in many cases large doses of morphia answered no better than small ones in relieving pain.—Mr. WALKER SMYTH, Dr. BENNETT, and Mr. JESSETT having spoken, the discussion was adjourned to the following meeting.

Dr. WALTER (Manchester) gave particulars of an abdominal enlargement in a girl aged thirteen which had been noticed for six months. The girl had rapidly lost flesh. The physical signs were those of ascites, and in the region of the umbilicus some hard nodular masses could be distinctly felt. There was no history of any sudden pain or change in the contour of the swelling. The diagnosis arrived at by all who had seen the patient was either tuberculous peritonitis or malignant disease of the abdomen with ascites. An exploratory incision proved that the fluid in the peritoneal cavity was entirely ovarian, and the masses referred to consisted of a multilocular cystoma of the left ovary. On its upper surface a round aperture a quarter of an inch in diameter was found, and through this opening fluid similar to that in the abdomen was seen to escape. The cystoma weighed 4 lb. 4 oz and the fluid weighed 9 lb. 6 oz. The girl made a rapid recovery.—The PRESIDENT thought Dr. Walter could not be said to have made any serious error in coming to the conclusion which he arrived at in view of the facts before him.—Dr. BANTOCK said it was not quite correct to speak of a case of this kind as "rupture," though this result might occur after a fall. Multilocular ovarian tumours were very prone to a colloid degeneration, owing to which a small hole gradually extending often occurred in the wall. By the formation of such a hole in a septum the loculi were thrown into one. He had pointed out some time ago that this was the mode of origin of unilocular ovarian tumours.—Dr. MACNAUGHTON JONES believed that a true rupture, apart from degeneration, could occur spontaneously; he had seen two cases.—Mr. JESSETT gave an account of an unusual case which he hoped to bring before the society in which a cyst ruptured, and the abdomen was found full of small free cysts. The case proved fatal.—Dr. WALTER briefly replied.

HARVEIAN SOCIETY OF LONDON.

The Dorsal Auscultation of Heart Sounds and Murmurs.

A MEETING of this society was held on March 7th, the Vice-President, Dr. J. E. SQUIRE, being in the chair.

Dr. WM. EWART read a paper on the Dorsal Auscultation of Heart Sounds and Murmurs. He dealt with the subject in great detail and corroborated the observations of Walshe. In particular he drew attention to the desirability of taking a fresh view of the subject of dorsal auscultation of the heart; for, though it probably had been studied by various observers, their results had not been published, and apparently no later account was available than that by Walshe. The statements of that great authority deserved to be tested

and confirmed by fresh observations; and although much immediate practical advantage could not be expected of the inquiry it would be satisfactory to feel sure that we possessed all the facts with which auscultation could provide us at the present time. A study of the conduction of the normal heart sounds must necessarily precede any study of the murmurs, but the method to be followed was the same in both cases, and implied a previous inquiry into the topography of the heart in connexion with the back, and into the intrathoracic anatomical relations which might favour or impede the conduction of sound vibration. An auricular and a left aortic auscultatory site suggested themselves in this way as it were, *a priori*, as anatomical sites; but other auscultatory sites were situated at a distance from the heart, and their recognition had been purely empirical. To these belongs the site at the lower angle of the left scapula, where auscultation was constantly being practised. For the auscultation both of heart sounds and of murmurs the rigid stethoscope was to be recommended. In the investigation valuable assistance had been received from Mr. Bertram Cooper, Mr. Scott Elliott, Dr. Sidney Ransome, and from Dr. Eric France, who, in a series of thirty children, had tabulated the results of his own auscultation of the heart sounds at the various sites. The paper dwelt in detail on the audibility of sounds and murmurs at the several auscultatory sites; the main results closely agreed with those which had been published by Walshe. Attention was drawn to the conduction of heart sounds and murmurs at the right base, apparently along the upper surface of the liver, a subject upon which further observations might probably throw interesting light. Meanwhile, the area at the left scapular angle still retained its prominent position among the dorsal auscultatory sites as supplying us with the most definite practical conclusions in connexion with the differential diagnosis of some of the cardiac murmurs.

Dr. SQUIRE thanked Dr. Ewart for bringing before the society a paper on so interesting a subject. He asked whether the patient in whom the cardiac impulse was observed in the back had a cavity in the lung. According to his (Dr. Squire's) observation an impulse synchronous with the heart's beat might be seen or felt in almost any part of the left chest—front or back—in cases of pulmonary cavities. The conduction of cardiac sounds to the back was often of more value in indicating the condition of the lung than in reference to the heart itself, though murmurs originating on the left side were most likely to be conducted backwards because of the position in which the heart lies. He had recently a case under his care in which a mitral presystolic murmur was plainly audible in the back. In connexion with murmurs heard in the back, he drew attention to the "whiffing" sound produced in the air tubes, which is systolic in point of time and might easily be mistaken for a true cardiac murmur. It is well heard just below the angle of the left scapula and is most distinct during inspiration. Though caused by the beating of the heart it is a pulmonary and not a cardiac sound.

HUNTERIAN SOCIETY.

Exhibition of Specimens.

AN ordinary (pathological) meeting of this society was held on March 13th at the London Institution, Mr. CHARTERS J. SYMONDS, President, being in the chair.

Messrs. William T. Partridge, Thos. Rushbrook, and E. B. Landon were unanimously elected Fellows of the society.

Mr. OPENSHAW showed a Congenital Sacral Tumour (and the child from whom it had been removed) presenting microscopically epithelial and striped muscle tissue. He also showed specimens of Sarcomatous and Cystic Tumours removed from the same region.—The President, Mr. Halliday, and Sir Hugh Beevor made remarks.

Dr. FRED. J. SMITH showed the Cranial Vault and Brain of a woman exhibiting the growth of a large Sarcomatous tumour which, starting from the brain, had perforated the dura mater and bone by several small processes and then formed a swelling as large as a foetal head beneath the scalp. The duration of the case had been less than a year from beginning to end, and yet the tumour showed considerable caseation (the microscope left no doubt as to its sarcomatous nature).—The case was discussed by the

President, Mr. Openshaw, Mr. Hallidie, Dr. Rutter, Dr. J. H. Sequeira, Dr. Turner, and Sir Hugh Beevor.

Specimens of Gall-stones causing obstruction which ultimately proved fatal were then shown by the President, Mr. OPENSHAW, and Dr. H. FOX.—The cases were discussed by Mr. Cotman, Sir Hugh Beevor, and Mr. Humphreys.

Mr. HOPE GRANT showed a specimen of Scirrhus Carcinoma, causing oesophageal stricture just above the stomach.

Mr. OPENSHAW showed a specimen of Cystic Sarcoma of the Kidney which had been hardened in formal. The specimen had been removed from a child aged three.—Sir Hugh Beevor and the President discussed the case.

The PRESIDENT showed specimens of Carcinoma of the Stomach and Liver taken from the body of a patient whom he had previously exhibited to the society as an illustration of the excellent result he had obtained by his method of performing gastro-jejunostomy; the patient lived in comparative comfort for over ten months after the operation had been performed.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.—Two Cases of Extradural Pressure on Spinal Cord.—Foreign Body in the Bronchus.

THE sixth meeting of the session was held on March 13th. The President in feeling terms spoke of the loss the society had sustained in the death of a past president, Dr. James G. Davey.

Dr. CHRISTIE showed a patient with Asymmetrical Development of the Cranium and Lower Jaw, with spinal symptoms; and another patient with Peripheral Neuritis, showing tropho-neurotic changes.—Drs. Firth and Clarke discussed the cases.

Mr. GREIG SMITH exhibited—(1) a large Sarcoma of the Breast; (2) Hydronephrotic Kidney, due, he considered, to pressure on the ureter, from a woman with extreme prolapse of the uterus; (3) Subphrenic Abscess Cavity, caused by a perforating ulcer in the stomach; (4) Malignant Stricture at the Ileo-caecal Valve; (5) Gall-stones from two recent operation cases; and (6) a small Calculus from the female bladder.

Dr. HARRISON exhibited a specimen of Necrosis of the Lower Jaw in a Polar Bear; and Fracture of the Base of the Skull in a Brahmin Bull.—Dr. J. G. Swayne and Mr. Ewens commented on the specimens.

Dr. MICHELL CLARKE read a paper, illustrated with numerous diagrams and specimens, on two cases of Extradural Pressure on the Spinal Cord (*a*) from inflammatory swelling in a case which presented symptoms of syringomyelia, and (*b*) from a localised tuberculous mass in caries.—Mr. BARCLAY described the operation he had performed in the former case, mentioning the great difficulty he experienced in stopping the excessive hæmorrhage.

Mr. PAUL BUSH read a paper on a case of Foreign Body in the Bronchus of a child aged eight years, and exhibited a steel hat-pin over three inches in length which had been expelled through the mouth three months after tracheotomy had been performed.—Dr. Fisher commented on the absence of lung symptoms, and Mr. Morton, Dr. Rogers, Dr. Newnham, Dr. Harrison, Mr. Barclay, Dr. Michell Clarke, Dr. Christie, and Dr. Firth considered various points in connexion with the paper.

LIVERPOOL MEDICAL INSTITUTION.

Cases of Laryngeal Paralysis.—Renal Calculus.—Supra-pubic Cystotomy for Vesical Hæmorrhage.—Death Certification and the Recommendations of the Select Committee of the House of Commons.

A MEETING of this society was held on March 14th, Mr. CHAUNCEY PUZEY, President, being in the chair.

Dr. PERMEWAN described two cases of Bilateral Laryngeal Paralysis. The first had a history of dysphagia combined with attacks of spasmodic dyspnoea. At first no oesophageal stricture could be detected, but even then there was complete bilateral abductor paralysis of the cords. Organic disease affecting both recurrent laryngeal nerves was diagnosed, and the patient eventually died from starvation. At the post-mortem examination a cancerous mass was found surrounding both recurrent laryngeal nerves. The second case was one

of bulbar paralysis, in which Dr. Permevan was able to watch the onset and progress of the laryngeal affection. The paralysis started with the abductors, and it was only after nine months that the adductors became affected. This, he observed, is only what might be expected from our general knowledge of laryngeal paralysis, but is in contradiction to the teaching of authorities on nervous diseases.

Mr. LARKIN read notes of a case of Renal Calculus in a woman where the symptoms closely resembled those of fissure of the anus. There were no symptoms referable to the kidney except a trace of pus in the urine, but, under chloroform, a slight enlargement of the right kidney was detected by palpation. The patient was relieved of all pain by removal of the calculi from the kidney.—The President, Dr. Carter, and Dr. Davies made remarks on this case.

Mr. GEORGE HAMILTON read a note on a case of Vesical Hæmorrhage for which supra-pubic cystotomy had been performed. He also showed a new apparatus for drainage.

Mr. F. W. LOWNDES read a paper on Death Certification and the Recommendations of the Select Committee of the House of Commons. After alluding to the heartburnings which this unremunerated duty had caused, both to the public and the profession, Mr. Lowndes quoted from a speech of Dr. Farquharson, M.P., and read a letter from Sir Walter Foster, M.P., in which both gentlemen expressed their sense of the importance of the subject, and of the value of any resolution which might be adopted by the members of representative and scientific bodies. Mr. Lowndes then went through the recommendations of the Select Committee *seriatim* and dwelt upon the importance of caution in giving death certificates, adducing instances which showed that carelessness in this respect facilitated wholesale poisoning; while, conversely, a little extra care might save life. He also urged that greater care should be shown by coroners in their informal inquiries, and that they should have power to remunerate medical practitioners in cases where they did not hold inquests.—Dr. HOPE drew attention to the importance of discriminating between mischief arising from defects in the law regulating registration and from evasion of the existing law. In Neal's case the medical man, registrar, and witness all seemed to have failed to comply with existing requirements. Dr. Hope considered that a fee should be payable by the governing body in respect to every death certified; this would conduce to greater accuracy, which was greatly needed. In the event of public medical certifiers being appointed, he did not think that the medical officer of health should be that officer, but an independent coroner's assessor might discharge such functions.—Mr. PUZEY, Dr. Carter, Dr. Whitford, Dr. Imlach, Dr. Permevan, and Dr. Davies also took part in the discussion which followed the reading of Mr. Lowndes' paper.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Traumatic Aneurysm of Aberrant Right Subclavian Artery.—A New Method of dividing Bone in Surgical Operations.—Exhibition of Specimens.

A MEETING of this society was held on Feb. 28th, Mr. SIMEON SNELL being in the chair.

Mr. PYE-SMITH showed a Breast removed that day from a woman aged ninety-one. It contained a growth which appeared to the naked eye to be a sarcoma. This had grown recently at the site of a small lump which had been present, it was believed, for sixty years, having followed an injury.

Dr. BLACK MILNE showed an almost perfect example of Congenital Asymmetry in a female child aged nineteen months. Full details and measurements were given. The patient was the first child of young parents who presented no anomalies in themselves, nor were any recorded in the case of their relatives. The right side was the larger, and the inequality was shown in the head, face, trunk, limbs, and in the following structures—viz., alæ nasi, palate, tongue, tonsil, and labium. On the right side the palpebral fissure was wider and the globe looked larger. There was cutaneous congestion on both sides, but more marked on the right. No varices or nævi were present. On the two sides the arteries appeared to be equal and there was no difference in the temperature. Six teeth were present on the right side and one on the left. Reasons were given for thinking that

there was deficiency of growth of the left half of the body as well as over-development of the right.

Mr. PYE-SMITH read notes of a fatal case of Traumatic Aneurysm of Aberrant Right Subclavian Artery. A man aged thirty years had fallen on his back from the top of a house. He had dyspnoea with signs of obstruction to the left bronchus, dysphagia, and absence of right radial pulse. After temporary improvement the dyspnoea and dysphagia increased, and the right carotid pulse disappeared. On the eighteenth day impending suffocation was relieved by tracheotomy and a long tracheal tube, but vomiting of blood occurred on the next day and he died the day following. At the necropsy a traumatic aneurysm was found in the posterior mediastinum on the aberrant right subclavian artery. This had caused pressure on the left bronchus, and later on the oesophagus, trachea, and right carotid artery. Finally, it had ulcerated into the oesophagus.

Dr. MORTON read a paper entitled "A New Method of Dividing Bone in Surgical Operations." The novelty he suggested was shown in an instrument with two opposing blades similar to bone pliers, but having a deeply indented cutting edge, the teeth being spear-pointed and sharp on either side. The lever handle, actuated by a strong closing screw, approximated the blades until the bone was divided. The dentated edge was applicable to chisels. Various sizes of them were exhibited. Sundry bones were experimented on with good results, the cut surfaces having a fairly even aspect throughout.

EDINBURGH OBSTETRICAL SOCIETY.

Exhibition of Specimens.—Frozen Sections and the Mechanism of Labour.—Some Measurements of the Uterus.—Walcher's Position.

A MEETING of this society was held on March 13th, Dr. A. H. FREELAND BARBOUR, President, being in the chair.

Dr. JAMES RITCHIE showed a Dimidiata Placenta; also an American Pessary for Prolapsus Uteri, a modification of the cup pessary, with telescopic stem attached to a pelvic band.

Dr. BALLANTYNE exhibited an Anencephalous Fœtus with Spina Bifida, to which amniotic bands were attached. The right thumb was poorly developed. This fœtus was female, and the fourth child of the mother. The previous child was also female, but was hydrocephalic and with absence of the right thumb. The first and second children were healthy males.

The PRESIDENT continued his paper on a Study of the More Recent Frozen Sections in their Bearing on the Mechanism of Labour and the Third Stage. As regards the engagement of the head, the received view is that the head is synclitic, the horizontal planes of the head coinciding with the horizontal planes of the pelvis, but in no frozen section is the head synclitic. In most there is more of the posterior half of the head below the plane of the brim as the head engages than of the anterior. (Saunders's and Barbour's sections show rather more of the anterior.) Pinard and Varnier advance the view that in normal labour the posterior part of the head is fixed and the anterior advances, as in the mechanism in the rachitic pelvis. The question is not settled; there is a fallacy, as the position varies according to the state of the cervix. Pinard and Varnier's frozen section was made in the horizontal posture, whereas the woman is usually in the erect position in this stage. As regards the third stage, Pestalozza gives two sections where the uterus had been emptied by artificial delivery, and thus it had shrunk after extraction of its contents, and had not been emptied by contraction of its walls. In the first section the uterus measures 8 in. by 4 in.; the anterior wall is 1 in. in thickness, and the posterior wall, to which the placenta is attached, only $\frac{1}{2}$ in. The posterior wall has not contracted or retracted. The second section was from a case of twins, where the mother died from sudden congestion of an enlarged thyroid; the first child was delivered by forceps, the second by turning. The uterus measures 8 in. by $4\frac{1}{2}$ in. by 5 in., and the fundus rises to 7 in. above the pubes. There is great diminution of the area of the uterus without separation of the placenta. The placenta are folded like a sponge, and yet with a diminished site there is no separation. Pinard and Varnier show a section of a uterus in the third stage. The case was one of triplets; the placenta of the twins is on the posterior wall, and that of the third child on the anterior wall. The section exhibits

the placental site shrunk, the placenta in folds or bulging at the borders, but not separated. The only place where there is a little separation is for one inch at the lower border. In a previous paper Dr. Barbour from his own work stated that the placenta did not separate till the beginning of the third stage and that there is no open space in the uterus at this time. In normal labour no separation takes place until retraction has occurred. During this retraction the uterine vessels are closed. In conclusion, Dr. Barbour discussed the general question of the knowledge gained from frozen sections in relation to labour in its clinical aspect—how these dealt with anatomy rather than with physiology, with position and not with movement, and with planes, not with a body in its general configuration.—Dr. HAULTAIN and Dr. BALLANTYNE spoke, and Dr. BARBOUR replied.

Dr. W. E. FOTHERGILL read a paper on the Height of the Fundus and the Shape of the Uterus when the Head is at the Brim and at the Vulva respectively. The results of measurements in thirty cases were that with the head on the vulva the fundus was one-third of an inch higher than in the former position, and that the uterus was narrower by one inch and had diminished by about one inch antero-posteriorly when the head was in the latter position.

Dr. W. E. FOTHERGILL also read a paper on Walcher's "Hanging Legs" Position, with special reference to its value where the perineum is in danger. Walcher's position is obtained by placing the patient across the bed with the hips at the edge, when the legs are allowed to hang down without touching the floor; a pillow can be placed below the buttocks if necessary. He had measurements of the diagonal conjugate in six cases, these were made under an anæsthetic, and comparison made between the results obtained in the lithotomy and in Walcher's positions. In the series there was an average increase of 0.93 cm. in the diagonal conjugate with the patient in Walcher's position.—Dr. BALLANTYNE alluded to a difficult high forceps case where he had endeavoured for about an hour to effect delivery in the lithotomy position; the assistants becoming tired he allowed the legs to hang down, and the head was then immediately and easily delivered.—Dr. BARBOUR had no doubt of the benefit of this position, but it was difficult to understand its rationale. An increased diagonal conjugate might not necessarily mean an increase of the true conjugate.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

Symmetrical Gangrene of Ears.—Cirrhosis of Liver in a Child.—Spindle-cell Sarcoma of the Female Urethra.—Epithelioma of the Cervix Uteri.

A MEETING of this Section was held on March 8th, the President, Dr. J. A. SCOTT, being in the chair.

Dr. H. C. TWEEDY exhibited the Heart and Lungs of a male patient aged thirty-five, who had suffered from Symmetrical Gangrene of the Ears. In the heart the left ventricle was hypertrophied, and the mitral valve narrowed, thickened, and covered with vegetations. The aortic valves were healthy, but the aorta itself was atheromatous. The right ventricle was greatly dilated and the tricuspid valve was surrounded with hard atheromatous nodules. There was an infarct of large size in the upper lobe of the right lung and one of smaller size in the left lung. The left kidney was enlarged and contained numerous cysts. The gangrene of the ears had commenced nineteen months ago, in the autumn of 1893, and in opposition to the contention that the case was one of Raynaud's disease, Dr. Tweedy urged—(1) the absence of typical paroxysmal pains; (2) the absence of defective circulation in the hands or feet; (3) the absence of vesicles, bullæ, or ulceration in the parts affected; (4) the steady continuity of the morbid process, there having been apparently no successive attacks with intervals between; (5) the age and sex of the patient; and, lastly, that the general condition of the circulation, as the result of the disease in the mitral valve and the atheromatous condition of the vessels, supplied a possible explanation for the morbid change that had taken place in the ears. As there was no history of rheumatism, it was possible that the condition of the heart and bloodvessels might have been secondary to the morbid process, which was considerably

advanced in the kidney.—Dr. McWEENEY asked whether the patient had any pain. He thought it might possibly be a case of Morvan's disease, and would like to know if the brain or spinal cord had been examined.—Dr. DALY said that he had been the cause of bringing this case forward. The man was very much worse in cold weather. He had seen his hands wrinkled with cold. He had showed the case to many within the last eighteen months, all of whom had diagnosed Raynaud's disease. He was at the Richmond and Adelaide Hospitals, and had no heart murmur then. When the disease commenced it was symmetrical. He suffered intense pain. He never had syphilis. He was twelve years in the army, being four in Ceylon. He was a strong, healthy man.—Dr. BENNETT stated that the gangrene had commenced in the early autumn, when there was not much cold.—Dr. WOODS saw the case at the Richmond Hospital a year and a half ago. He had seen three other cases of Raynaud's disease, all of which were men, but this was the most pronounced. He had examined the man's heart and had found a mitral systolic murmur. He believed it was a case of Raynaud's disease the symptoms of which were aggravated by heart disease. He recommended him to wear ear-caps over his ears. As well as he remembered, the right ear was worse than the left.—Dr. PARSONS wished to know where the man was when it occurred. He thought the necropsy had not done much to clear up the case. He did not understand how the circulation in his ears was so bad as to cause gangrene in spring and summer, for there appeared not to be any dropsy of the extremities, which was one of the first signs of cardiac failure. He wished to know if the urine had been examined for methæmoglobin, which had been found present in cases of Raynaud's disease.—Dr. DALY said that the disease commenced one year and eight months ago. He was living in Dublin at the time. He never suffered from chilblains. When he examined the urine there was no albumen in it. The man worked inside a store and was not exposed to the cold.—Dr. TWEEDY, replying, said that the necropsy was made under great difficulties, and did not last more than ten minutes. He had been unable to get a portion of the ear. The brain and spinal cord had not been examined. There was no definite pain till the hard masses of slough formed, which then caused him pain to lie on the ear. He still thought the cardiac disease sufficient to cause the condition of his ears. It could not have been a frostbite, as the disease commenced in the early autumn. The heart trouble must have been pretty chronic from the post-mortem appearances. He had only seen one other case of Raynaud's disease. It was in a child, and the little toes were gangrenous, and in addition there were vesicles and bullæ present. The child had also paroxysmal pain. In this case the hands and feet were frequently very cold. He had not examined the urine for methæmoglobin as the man had only been a short time in hospital and died suddenly.

Dr. O'CARROLL showed a Cirrhotic Liver taken from a child aged eight years. The specimen was remarkable by reason of the fact that from the under surface protruded downwards a large mass consisting of nut-like islands of hepatic tissue surrounded by thick bands of glistening fibrous tissue, and which during life had given rise to the suspicion of a tumour of the liver or in its neighbourhood. No previous history of the patient could be obtained sufficient to settle the question of causation, but the large amount of peri-hepatitis seemed to hint at a syphilitic origin of the disease.—Dr. McWEENEY and Dr. PARSONS alluded to the difficulty of diagnosis in the case. Dr. McWeeney had only seen the naked-eye appearance.

Dr. McWEENEY showed an example of Spindle-cell Sarcoma of the female uterua and also a specimen of Epithelioma of the cervix uteri, with sections.

METROPOLITAN DISPENSARY.—The annual meeting of this institution was held in Fore-street, E.C., on March 15th, Mr. J. J. Baddeley, the treasurer, presiding. The committee's report showed that the visits paid by the medical staff to patients in their own homes were 500 fewer than in 1893, and explained the fact by the general improvement in the public health. During the year 13,182 patients came under treatment. The total expenditure was £883, and the balance in hand at the end of the year was £403. Grants of £100 were made to the dispensary by the City Parochial Foundation, and also by the Cripplegate Foundation; the Clothworkers' Company subscribed £20 and the Saddlers' Company £10. The usual votes of thanks were accorded to the treasurer and medical officers.

Reviews and Notices of Books.

Transactions of the Epidemiological Society of London. New Series. Vol. XIII. Session 1893-94.

THE Transactions of this Society always afford good reading, but the latest volume presents points of special interest. It contains nine papers and a supplement, and we must confess to having, like the novel reader who reads the last chapter of a new novel first, turned first to the supplement; or, rather, in strict accuracy, to having done so immediately after reading the President's inaugural address upon the History of Epidemiology in England. In that address Dr. Payne drew attention to an important, though little-known, contemporary account of the great Plague of London in 1665, and suggested that the Society would be doing excellent service to medical literature were it to print this treatise in full or in part. This suggestion the Society has carried out, and has printed the whole treatise, publishing it as a supplement to the present volume of Transactions. "Loimographia, or an Experimentall Relation of the Plague, of what happened Remarkable in the last Plague in the City of London....." by "William Boghurst, Apothecary in St. Giles'-in-the-Fields, London, 1666," has hitherto lain in obscurity as No. 349 of the Sloane MSS. in the British Museum, and now appears in print for the first time. Its existence, however, has been known, and it has been drawn upon by several writers. Defoe is thought to have made use of it for his great story of the Plague; Dr. Payne has himself quoted it in his article upon the Plague in the "Encyclopædia Britannica"; Dr. Creighton describes it in his "History of Epidemics"; and it has even been alluded to in Germany by Haeser in his "Geschichte der Medizin." But these facts in no way detract from the real service which the Epidemiological Society has rendered in now printing the treatise in full.

Of the author comparatively little is known, save that he was an apothecary at the sign of the White Hart in St. Giles'-in-the-Fields, and that when all who could were flying from the pestilence he remained and attended the sick without fear or faltering—a fact on which he insists with pardonable pride. His epitaph, we learn from Dr. Payne's introduction, declared that "he was an honest, just man, skillful in his profession and in the Greeke and Latine Tongues, delighting in the study of Antiquity." This is fully borne out by the present treatise, which contains much evidence of Boghurst's acquaintance with the classical medical writers, from Hippocrates downwards. But while accepting the medical traditions of his time, he was far from bowing down before them, and was clearly able to make original observations for himself. Clinically, he was evidently a close and acute observer. The work is divided into twenty-eight chapters: on the causation, prognosticks, diagnosticks, good and evil signs of the Plague, and so forth. Of these the first is the most interesting, in which the author discusses "the nature and causes of the Plague as a student in Physick." In this he goes curiously near what must now be accepted as the true explanation of the origin of the disease when he writes: "The essence of the Pestilence is lodged in some peculiar venome that is contrary and destructive to the vitale principles of man. That this venome is a body or concretion of many little bodies, though very subtle and invisible, can bee no doubt for those that have outgrown Aristotle and are acquainted with the Epicurean or corpuscular philosophy." Of the two so-called schools of contagionists and localists Boghurst must be counted a stout supporter of the second. He sums up his views as follows: "The Plague or Pestilence is a most subtle, peculiar, insinuating, venomous, deleterious exhalation arising from the maturation of the ferment of the faeces of

the earth extracted into the Aire by the heat of the sun, and diffused from place to place by the winds, and most times gradually, but some times immediately, aggraving apt bodies." This is not a happy example of the author's literary style; as a rule, when he escapes from the medical jargon of his age, he writes in all the simplicity of good Saxon English. He further displays a commendable mixture of common sense with his technical knowledge, and a deep conviction in the correctness of his own views and readiness to uphold them against all who may differ from him, while a leavening sense of humour makes his treatise far more readable than many old medical treatises. His account of the rise and early spread of the Plague in London differs in many important points from that given by Hodges, who has been the authority for most subsequent writers upon this epidemic, and, if for this fact alone, the Epidemiological Society was justified in its action, and is to be congratulated upon giving permanent form to a really valuable work.

Dr. McVail's paper upon the Aërial Convection of Small-pox from Hospitals deals with one of the most burning questions of recent years, and led, it may be remembered, to an adjourned discussion of considerable interest. Beginning with an account of the classical controversy in the last century between Haygarth and Waterhouse concerning an outbreak of small-pox in Charleston, this paper goes on to discuss some of the more important evidence published in recent times as to the part which the air plays in spreading the contagion of small-pox. Without adding anything new to our knowledge upon this subject, the paper is nevertheless a thoughtful essay upon a most important topic. The publication of Mr. W. H. Power's investigations at Fulham, now fourteen years ago, brought this question to the forefront of practical public health questions, and the additional evidence from at least half a dozen metropolitan hospitals and as many in the provinces has only tended to confirm the conclusions he then formed. With these Dr. McVail is in full accord, believing that aerial convection does occur from hospitals, though not denying to personal communication some share in the explanation of "special area" incidence of small-pox.

The paper entitled a Contribution to the Epidemiology of Cholera in Russia, by Dr. F. G. Clemow, is based on a careful study of the epidemics of 1892 and 1893, and although the maps and charts which were used to illustrate it have not been reproduced, it is written so lucidly that their absence is less to be regretted. The paper is one of no small interest and importance. In many respects the conclusions arrived at are in conformity with previous experience—e.g., the comparative immunity in the second year of an epidemic enjoyed by a district that has suffered severely in the first year; the brevity of the incubation period of cholera; and the greater fatality in children and elderly persons than in the middle-aged. Some interesting details are given as to the dissemination of the disease in a country where bazaars and fairs lead to large and shifting gatherings of people. That the disease is communicated from person to person Dr. Clemow is convinced, but he guards this view by admitting that the poison gains entrance by the alimentary canal. Instances of its conveyance by families and of contamination by water-supply are cited.

The paper upon the Distribution of Influenza Mortality in England and Wales in Recent Years is a careful statistical study by Dr. Franklin Parsons. It is illustrated by a number of useful diagrams and tables. Dr. E. D. Dickson of Constantinople writes an interesting account of the cholera in Mesopotamia and Syria, and communicates the report upon cholera in Persia, written by Dr. Camposampiero, Ottoman sanitary delegate at Teheran, to the Constantinople Board of Health.

Handbuch der Physiologischen Optik (Handbook of Physiological Optics). Von H. VON HELMHOLTZ. Zweite Auflage. 9te und 10te Lieferungen. (Second edition, 9th and 10th parts.) Hamburg und Leipzig: Leopold Voss. 1895.

WITH these two parts, embracing 160 pages, the late Professor Helmholtz's celebrated treatise is nearly brought to a close. In a short preface Dr. Arthur König of Berlin states that the author before his lamented decease believed that he had practically completed the editing of the second edition, the succeeding parts requiring little alteration or addition. The "Physiological Optics," it must be understood, was original in its conception, was founded largely on the experiments and reasonings of its author, and was not intended to be an encyclopædia of optical science. It has proved to be, from the precision of its statements and the novel manner in which the phenomena of vision were treated, a storehouse from which all subsequent writers on optical subjects have largely borrowed, and which constitutes the solid foundation on which the physiological side of optical science mainly rests. The two parts now before us contain the subjects of the rotation of the eyes mathematically treated; the sense of position in space as determined by the visual sense; the explanation of various illusions of the visual sense; the consideration of the blind spot, of unilateral vision, and of the stereoscope and stereoscopic vision. The work is worthy of its distinguished author.

The Uric Acid Diathesis: Gout, Sand, and Gravel. By DR. F. LEVISON (of Copenhagen). Translated by Dr. LINDLEY SCOTT. London: Cassell and Co. 1894.

THIS work has received such a favourable reception in other countries that Dr. Scott was encouraged to translate it into English, believing that it would receive a welcome in this country. As the translator observes in his preface: "It may be regarded as a logical summary of the more recent researches on the pathology of uric acid, and on the action of various remedies recommended in the treatment of this diathesis." After a full description of the most practical methods of estimating uric acid, the formation and physiological signification of this body is carefully considered. The conclusions at which Dr. Levison has arrived are interesting. He lays special stress on Horbaczewski's observation that there exists a constant proportion between the number of white corpuscles in the blood and the amount of uric acid secreted. He states that the amount of uric acid excreted in twenty-four hours is not influenced to a great extent by food, but adds that the easily digestible animal albumens set up digestive leucocytosis and formation of uric acid much more quickly than the vegetable albumens, which are difficult to digest. Other interesting sections are devoted to the consideration of the subject of uric acid in the blood and the chemical compounds of uric acid in the blood and urine.

Turning to the clinical side of the question, the etiology, pathogenesis, symptomatology, course, and pathological anatomy of gout are fully and admirably described. Prophylaxis and treatment occupy a full share of attention and many useful hints and valuable information are given. "Sand and gravel" are finally considered and the treatment fully discussed. The work is capitally translated, and to those who are especially interested in this branch of medicine will prove most acceptable and well repay perusal.

Degeneration. By MAX NORDAU. London: Heinemann. 1895.

Atas parentum, peior avis, tulit
Nos nequiores, mox daturos
Progeniem vitiosiore.

THIS is Dr. Nordau's despairing cry—and a very old one; but, in spite of the trouble he has been at to justify it, we venture to think he is mistaken. Dr. Nordau will probably

include us among the "grapho-maniacs who dominate the entire press" for venturing to disagree with him in his conclusions, even if to do so is to write ourselves down as degenerate. That there undoubtedly does exist at this time a school or sect—call it what you will—which delights in sex problems, strange idiosyncrasies of dress, eccentric drawings, and mystical writings, among other things, no one can help seeing; but the same state of things has always been present, more or less, in every age. Everyone knows the excesses that were fashionable in ancient Rome and Athens; strange Oriental religions, affording scope for every variety of "mania" (the reader will find a list on page 242), were imported, and everything that could in any way minister to the pleasures of either mind or body was systematically employed. Coming down to the Middle Ages we find the same thing. Flagellants and mystics of all kinds gave way to the wildest excesses; and so the story unfolds itself through the Puritan excesses, on the one hand, and the court dissoluteness, on the other, of the seventeenth century to the appalling outburst of the French Revolution and the Napoleonic idolatry of the eighteenth century. Later developments have certainly occurred with startling rapidity in the last forty years or so, but where we venture to join issue with Dr. Nordau is in his over anxiety to attribute the taking pleasure in almost any form of art or mental culture to degeneration. Take his account of the degenerate's house. Old china, silver ornaments, Oriental carpets—the possession of anything, in fact, that is prized for its colour or design is a sign of a weak mind. "All is one discrepant jumble; the unity of abiding by our historic style counts as old fashioned and Philistine." We cannot see why a person may not take pleasure in the different styles of art or what there is of degeneracy in a dislike to monotony. Let anyone compare the style of a modern room furnished and decorated by a person of taste with the drawing-room of "the fifties." Here was one definite historic style, and what a style—the white and gold paper, the elegant suite of rosewood and Berlin wool work furniture, the Brussels carpet, with the stone-coloured ground and sprawling pattern of virulent red and pink roses as big as cabbages all over it, and the round table with the drawing-room books on it, all these made up of a "composition"; but where was "the feeling of repose"?

Dr. Nordau sees degeneracy in everything except the music of "Cavalleria Rusticana." He falls foul of Rossetti's fondness for refrains. This was a characteristic of old poetry which was handed down by oral tradition, the refrain being like the large beads on a rosary—a sort of milestone to mark the point the reciter had arrived at, and though, through the invention of printing, it has lost its original point, its use is still a perfectly legitimate way of giving an old flavour to a poem, just as the use of a scale with a whole tone between the leading note and the tonic is a legitimate way of giving an old flavour to music. To call it "echolalia" is absurd. If we go on Dr. Nordau's principle we can find mysticism in the most unlikely quarters—e.g.:

"I see Jerusalem and Madagascar,
And North and South Amerikee,
And the British fleet a-riding at anchor,
And Admiral Napier, K.C.B."

Now here is megalomania and echolalia and all the other characteristics of literary mattoids. Observe the mysticism. The author could not have really imagined that little Billes was able to see all these countries, but with the weird transcendentalism that belongs to the degenerate he wished to include the whole world in the vision of his character. So he starts with Jerusalem, the mediæval centre of the earth, and then goes on to Madagascar, where flourish the Cryptoprocra and many another strange beast, which by their structure carry us back to prediluvian days; then Amerikee,

with its traditions of Atlantis and the isles of the blessed; and then, with the inconsequence which is so marked a feature of the mystic, he links with Amerikee the British fleet and Admiral Napier, K.C.B. As Dr. Nordau says: "There is no connexion between these phrases. They are strung together simply because they rhyme. It is a startling example of echolalia."

That the fever of degeneracy will wear itself out there can be no doubt; just as the activity of a bacillus is put an end to by excess of its own products, so the activity of the modern school will bring about its own death. We cordially recommend a perusal of Dr. Nordau's book both for its extreme interest and as an example of the pitfalls into which a really able man may fall by pushing a theory too far.

The translator's name is not given, but the work has been done exceedingly well.

LIBRARY TABLE.

The Aseptic Treatment of Wounds. By Dr. C. SCHIMMELBUSCH. Translated from the Second German Edition by ALFRED THEODORE RAKE, M.B., B.S., F.R.C.S. London: H. K. Lewis. 1894. Pp. 250.—Aseptic, as opposed to antiseptic, surgery is daily increasing the number of its adherents in this country; but the success of asepticism depends on the thoroughness of the purification of everything that may come into contact with the wound, and this is by no means easy. We therefore welcome the appearance of the English translation of this little book of Dr. Schimmelbusch, as in it are given clear and detailed directions for rendering aseptic the surface of the body to be operated on, the instruments to be used, and the dressings to be applied to the wound. It is copiously illustrated, and certainly it is a very good representation of the methods of aseptic treatment. A copious bibliography of the subject is appended. The style of Mr. Rake's translation is good and readable.

Urinary Surgery. By E. HURRY FENWICK, F.R.C.S. Bristol: John Wright and Co. 1894. Pp. 219.—This volume is a member of a series of "Epitomes of Modern Surgical Progress," and is intended to be a *résumé* of the recent literature of the surgery of the urinary organs. Within the last few years changes of great importance have been made in this department of surgery, and further progress, in details at least, is taking place almost daily. A work embodying these recent changes can hardly fail to be useful, and Mr. Fenwick's book certainly goes far in the direction of accomplishing what it claims. It gives summaries of more than 300 papers, and in each case gives the reference to the original article, so that if further information is needed it can be easily obtained. Mr. Fenwick also contributes "editorials" on special subjects, such as Tumours of the Bladder, where mere abstracts of published papers would fail to give an exact account of the present state of the subject.

Manual of Diseases and Deformities of the Spine. By K. L. SWAN, F.R.C.S. Irel. Dublin: Fannin and Co. 1894. Pp. 194.—The diseases and injuries of the vertebral column are of so much importance and are so frequently met with that it cannot be denied that they are deserving of a special treatise. The work before us deals with all the ordinary forms of disease of the spine, and includes chapters on the paralysis consequent upon spinal disease, railway spine, and torticollis. In the description of the treatment of spinal caries an account is given of the "hammock" method of applying a plaster jacket, which, for some cases at least, is certainly to be preferred to the more usual method of suspension. The work is illustrated by thirty-three lithographs, which have a pleasing but certainly somewhat novel effect.

MAGAZINES FOR MARCH.

Clinical Sketches.—The third number of this magazine is up to the level of its predecessors. An article which will be read with melancholy interest is by the late Mr. Hulke, and is an account of a case of Malignant Disease of the Colon in which the presence of a large concretion formed by charcoal and bismuth blocked for a time the sigmoid flexure, causing obstruction and masking the presence of the original disorder. An obituary notice of the late President of the Royal College of Surgeons of England is accompanied by an excellent portrait.

The *Strand Magazine* contains several articles of interest—for instance, one upon the Manufacture of Explosives and one upon Eccentric Ideation, and an exceedingly poor story, with medical details, entitled "The Silent Tongue." This story is one of a series of medical stories now appearing in Mr. Newnes's popular paper, and none of these have been particularly good. We are tempted to think that in the story with medical motif the attempt at accuracy of detail detracts from verisimilitude.

The Englishwoman.—Miss Ella Hepworth Dixon is responsible for the appearance of a new monthly magazine intended to meet mainly the taste of feminine readers. As is now becoming the fashion in our lighter periodicals, the serial is dispensed with, but there are several complete stories, the most noticeable of which is in dialogue form by Miss Violet Hunt. Mr. Hitchens deals in a healthy manner with the case of a decadent boy, and all medical men, recognising the extent to which this disagreeable class has multiplied, must welcome the signs of general repulsion which are now becoming manifest.

ERRATUM.—In the review of Baldy's "American Text-book of Gynecology," which appeared in our issue of March 2nd, we omitted to mention that Mr. F. J. Rebman, 11, Adam-street, Strand, is the London publisher.

New Inventions.

NEW DENTAL FORCEPS.

ANTISEPTIC precautions have been long recognised to be as necessary in dental as in surgical operations. Cases have been put upon record where specific diseases, and syphilis in particular, have been inoculated by the use of unclean instruments. When dental forceps are put in chemical solutions for the purpose of sterilisation—though it is not necessary to render the joint aseptic as in instruments used for an operation like laparotomy—experience shows that the

solution quickly finds its way into the joint, and mixing with blood and saliva, which trickle down the blades, collects there and causes rusting of the joint. The forceps thus becomes stiff and dirty, it being impossible, short of sending it to the makers, to take the blades apart. It is hoped that the instrument with a lock joint which the Dental Manufacturing

Company (Lexington-street, Golden-square, W.) have made at my suggestion will overcome this, and will ensure thorough and easy cleansing.

J. SEFTON SEWILL, M.R.C.S., L.R.C.P., L.D.S.
Cavendish-square, W.

THE VENTILATION OF PLACES OF ENTERTAINMENT.

THIS has been a very hard season for all places of entertainment; and the problem of warming and ventilating buildings where large numbers of persons congregate has rarely offered so many difficulties. There is one place, however, where special advantages are enjoyed. As a rule the crowding of spectators together in a limited space is the chief cause of trouble. At Olympia it may be said that the space is almost unlimited. The difficulty here is the other way round; there is no danger of the place becoming too hot through overcrowding. The great hall measures 650 ft. by 400 ft., and is 130 ft. high. Though it would be possible to accommodate 10,000 spectators such a number is not likely to attend; but when we consider that there are 2500 performers it may often happen that the hall would contain, including the performers, some 10,000 persons in all. Even then the difficulty would be that of warming rather than of ventilation, for 10,000 people would still enjoy about 3000 cubic feet of air each. It is, therefore, important to note how the warming is accomplished. For this purpose it has been necessary to lay pipes which have a total length of nearly ten miles. These pipes contain steam under pressure. They are in the flooring of the passages and in the walls, thus heating the body of the structure. Then, at various intervals, and especially in places where cold draughts are likely to occur, coils are placed which can be fed with steam from the pipes, and a sort of damper enables the attendants to regulate the amount of heat the coils are to give. There are in all about 250 such coils. But this is not all; the large sheet of water, which is so useful to cool the building in summer, adds to the heat in winter. This water is warmed by the Rosher system. This consists of a system of steam jets which draws the water from the canals. The water is heated by the condensation of the steam, and is then injected back into the lake or canals through the bottom of the tanks by "spreaders." Nine heaters are thus employed, and a systematic circulation of heated water established. The heaters have also each an air valve by which air is forced into the canals, and this helps to keep the water fresh. By these means the temperature of this vast volume of water can be raised at the rate of 2° F. per hour, and is generally maintained at a temperature of 60°. Once a fortnight, on a Saturday evening, the whole of the water is cleared out and the bottom of the tanks carefully swept. It then requires eighteen hours to fill them afresh with a constant flow through a nine-inch inlet pipe.

The great secret of the even and pleasant temperature that pervades this vast building is the fact that the system of warming is kept in full activity day and night during the whole of the season. It requires three days to warm the building, and then it is never allowed to become cool again. This is the secret of true comfort and the reason why houses in cold climates—Russia, Canada, &c.—are much warmer and more comfortable than in such moderate climates as that of England. At Olympia the heat is if anything higher in the passages than in the auditorium, and the heat is maintained day and night. Such is also the case in a Russian house; but in an English house the passages, hall, staircases &c. are rarely if ever heated, and in the rooms the fires go out at night. Thus there is no uniformity, but draughts and constant changes of temperature in different parts of the building. At Olympia, in the huge auditorium between the spectators and the stage, there is a vast surface of warmed water which constitutes an excellent medium for retaining and distributing heat in a slow and uniform manner. The dry and unwholesome air that is the consequence of over-heating and the foul air that results from overcrowding and inefficient ventilation, are dangers that too often prevail in places of amusement. The absence of any such inconvenience and danger has been not the least of the attractions which Olympia offers to the public.

THE LANCET.

LONDON: SATURDAY, MARCH 23, 1895.

A SPECIES of duel has lately been fought between the General Medical Council, on the one hand, and the Obstetrical Society, on the other, and has been rendered triangular by the interposition of the opponents of the registration of midwives. The feelings which have been excited on all sides over this subject have been, we think, unnecessarily heated and bitter. Certain distinguished leaders of the obstetric world—Sir JOHN WILLIAMS, Dr. PLAYFAIR, Dr. CHAMPNEYS, Dr. HERMAN, and not a few Irish and Scotch physicians,—who doubtless thought they were doing a kindly and useful action in giving their countenance to a certain amount of training in midwifery and providing for the certification of women who assume the title of midwife and practise among the poor,—have, it would seem in the opinion of some, been practically brought before the Council on a charge of infamous conduct in a professional respect. Dr. PLAYFAIR uses the strongest adjectives he can find—"outrageous," "insulting," &c.—to characterise the action of the Council. There is certainly some excess of imagination and of language on this side. The other is not much behind it. Dr. LOVELL DRAGE, for instance, does not see why the Council should mete out treatment to the Obstetrical Society different to that which it administers to gentlemen who employ unqualified assistants. There is in some of the correspondence which has been going on a want of acquaintance with the action and views of the General Medical Council which we should scarcely have expected in leaders of the profession with regard to such questions. Thus, Dr. PLAYFAIR says that, "so far as he knows, the Council has expressed no opinion on the examination and registration of midwives," the fact being that the Council has expressed many times, often in response to Government, its opinions on these subjects in the last twenty years.

Dr. PLAYFAIR does but scant justice to the General Medical Council when he proceeds to urge that it has heard only one side. To take only the last year as an example, the Council was approached by the advocates of both sides, as will be seen by referring to the published Minutes for 1894. Thus, at its May meeting the following rider to a verdict of a coroner's jury was received from the Home Office for the consideration of the Council: "The jury desire most strongly to censure JANE RUGG for not calling in medical assistance upon difficulties arising on the deceased giving birth to a child, and are of opinion that the Legislature should interfere to prevent women acting as midwives unless trained and certificated for such purpose." On the other side memorials reached the Council in numbers protesting against any regulation enabling persons to practise midwifery who were not fully qualified to practise medicine, surgery, and midwifery. It may be true that the Council at

its last few meetings has been mainly appealed to by the party opposed to legislation; but that is probably because the opposition is of recent origin. It is only within the last few years that any persons have been found to maintain that the midwifery of the very poor can all be done by medical men or fully qualified medical practitioners, and that there is no need of, or justification for, legislation to regulate the use of the term "midwife" by women who practise as such among the poor. Dr. WILKS has pointed out that there is some confusion between two distinct things which in England have always been well distinguished—the midwifery of an educated and fully qualified practitioner and the "midwifery" of a woman without special training, or with very little, who has made herself useful and acceptable to poorer neighbours who in their hour of need cannot afford for obstetric services the minimum fee required by medical men. The question whether the tragedies in the hands of ignorant midwives which so shock the public from time to time can be got rid of without legislation for the training or, at any rate, for the registration of midwives is one that cannot be settled offhand. In any case, however, it is a strange thing for the leaders of the Obstetrical Society to say that the Council hears one side only and has never expressed opinions on the fundamental question in dispute. We venture to recommend to Dr. PLAYFAIR a study of the minutes of the General Medical Council bearing on this subject, beginning, say, twenty or twenty-one years back. He will see many indications of respectful interchange of opinion between the scientific society of which he is an ex-President and the Council, which contrast favourably with the somewhat heated language which has lately obtained, and which seems to have raised fears of martyrdom in the President and members of the society.

In requiring that the language used in the certificates of the Obstetrical Society shall be such as not to imply licence to practise, the General Medical Council is only consistent with its own contention throughout, and with the obvious fact that the document given by the society has no legal value. Sir JOHN WILLIAMS says the word "diploma" is used in testimonials given to successful brewers. Even if this be true, it does not justify its use by the Obstetrical Society acting as an examining body. The Council cannot be said to have acted with undue haste. It has given repeated hints as to its objections to the document issued by the Obstetrical Society, which we publish on another page, and of which Dr. PLAYFAIR's version in a recent letter to us is a somewhat imperfect copy, though even in that form the owner of the diploma is styled "a skilled midwife," and it has not asked more than such a modification of language as shall make it clear that no legal licence to practise is conferred. Dr. LOVELL DRAGE himself will, we fancy, be satisfied if the document bears this on its face. We are glad to gather from Dr. PLAYFAIR's letter alluded to above that the society has resolved not to issue any more "diplomas" until a form is decided upon satisfactory to the General Medical Council. Under these circumstances we see reason to hope for a speedy disappearance of the somewhat strained relations at present existing between the General Medical Council and the Obstetrical Society. For our part we entirely acquit the

society of any purely selfish motives in this matter, and believe, as Dr. PLAYFAIR says, that they would gladly give up to others the work of examining midwives. In conclusion, let us add that THE LANCET always has been, and always will be, jealous of the rights of the general body of the profession and zealous in protecting their true and best interests. The question of the registration of midwives is undoubtedly a difficult one, but we do not yet despair of a solution of the difficulty which will be in accordance with the dictates of humanity and satisfactory to the whole body of our profession.

EGYPT and Algeria witness a large exodus of their winter visitants during the month of March, the melting of the snows in the Alps is the signal for the gradual dissolution of the winter colonies of Davos and St. Moritz, and during April the Riviera and southern French resorts become gradually deserted. This change from winter to spring quarters raises many difficult questions for the chronic invalid and his advisers, and at some of these difficulties we propose to glance, without attempting to lay down any hard-and-fast lines in a department of practice where individual idiosyncrasy counts for so much and where the special experience of the regular medical adviser is so important. The first question that naturally arises is why the invalid should leave his winter quarters at all. He has done well, let us assume, at Mentone, St. Moritz, Malaga, Luxor, Algiers, or Madeira. Why, then, leave a resort that has been proved favourable to his malady? The answer to this question is not quite so obvious as it may to some appear to be. It is true that a summer sojourn in Egypt or Algeria is practically impossible for the European invalid, but the same statement cannot be correctly made regarding the Alpine resorts or Madeira. There are some authorities with large special experience who hold that the summer climate of Davos or the Engadine is just as favourable for pulmonary complaints as the climate of winter. We believe this opinion to be to a considerable extent mistaken, but it is not manifestly absurd. Then, again, it is not very unusual for the winter visitant to Madeira or the Riviera to take to the hills at the approach of summer, and there encounter the hot season. Yet, we take it, the attempt to persuade the average invalid to make a permanent residence of his winter quarters is always predestined to failure. He longs for change, he yearns for ever so brief a sojourn in his own country, and he is deeply convinced that even the most favourable climate is not equally favourable at all seasons of the year. These feelings are not only perfectly natural, but may be defended on strong scientific grounds. Most sanatoria are—to put it plainly—dull to a degree, and the hackneyed round of medical treatment, regulated hygiene, and stereotyped amusements becomes to not a few individuals a hardly tolerable boredom. This boredom would be to many absolutely unendurable if there were no prospect of speedy release from it. Then, while there is much to be said for the principle of finding the climate that suits the invalid best and keeping him there, it is quite probable that there are cases with regard to which climates, like drugs, after a time lose their beneficial effects.

But the most solid ground for approving of a change of quarters at the end of winter is the incontestable fact that season may make all the difference between a good climate and a bad one, and that it is not as a broad principle true that because a climate is beneficial in winter it is likely to be equally beneficial at all seasons. Most of the southern sanatoria are beyond question much too hot in summer for British invalids. Then, to take the most disputable case, it is not a fact that the climate of the Alpine resorts is as favourable to pulmonary complaints in spring, summer, and autumn as it is in winter. The average of settled sunny weather is certainly higher in summer, there is less wind at this season, and the relative humidity of the air is less. These facts seem to us incontestable, and are quite consistent with the contention that the Alpine sanatoria are in certain cases good summer resorts. But the attempt which has often been made to prove that summer is as favourable a season as winter, and that invalids are extremely foolish to leave their winter quarters at the approach of spring, seems to us most injudicious.

Assuming, then, that invalids are, as a general rule, quite justified in their usual practice of seeking a change at the end of winter, various important questions arise. When should the change be made? Should it be made abruptly or gradually? What are the most convenient intermediate stations between winter quarters and the home country? The first question does not admit of any very precise answer, as so much depends upon the patient and so much upon the resort in which he has spent the winter. Few invalids remain south of the Mediterranean after the end of March; in the Alps the melting of the snows is generally taken to mark the transition between the seasons; while residence in the resorts of the Riviera or Southern France may be prolonged far into April or even later. As regards the second question, it is probable that abrupt transitions are more fraught with risk at the end of winter than at the beginning. An invalid may proceed with comparative impunity directly from England to the Alpine stations, but it will be well when possible to make the return journey in a more deliberate manner and to linger for a time at some intermediate station.

This leads us to the last point, What are the most convenient intermediate stations? To those who have wintered in Cairo or up the Nile, Corfu may be recommended, or Palermo, or Malaga. From Algeria recourse may conveniently be had to Ajaccio or Hyères. It must be remembered that none of the Italian resorts possess good spring climates, except the resorts of the Riviera—viz., San Remo, Bordighera, Allassio, Pegli, Nervi, and Rapallo. Those who have wintered in the Riviera have not, as a rule, much difficulty about an intermediate station, as they can stay in their winter quarters until the time has come when they can safely make the homeward journey by easy stages. The case of the Alpine sanatoria is more difficult, as a thoroughly satisfactory spring climate scarcely exists in Switzerland or Northern Italy. Among the places that may be recommended at this season, but with considerable reservations, may be mentioned Bex in the Rhone Valley, Montreux, and Gardone Riviera on Lake Garda. Spring is, indeed, a treacherous and most unsatisfactory season for the invalid over a large

part of Europe, and an ideal spring climate is still to seek. It will be well for the invalid to remember that as this is his most trying season at home, so is it in a large degree even in the most favoured of foreign resorts. He must relax none of his usual precautions, and must remember that the combination of bright sunshine with cold winds, which is so characteristic of the spring climate of most health resorts, is for him a peculiarly perilous one. Spring is the season *par excellence* for the ravages of pneumonia at home, and it is then also that the chronic pulmonary invalid abroad is most prone to those inflammatory complications which do so much either to imperil his life or to retard his recovery.

APPLIED science has its disadvantages as well as its advantages. The introduction of steam as a source of motive power brought with it a series of disasters caused by the sudden unloosing of the pent-up forces in the steam boiler through some defect in its construction; coal gas, since it was adopted as an illuminating agent, has introduced its share of dangers, though it must be admitted that accidents from this cause are rarer than they formerly were; while its competitor, electricity, since it has been laid down for lighting purposes, has actually been credited with manufacturing sodium beneath our pavements, which in contact with water has fired and ignited its rival, which, so it is asserted, has leaked from the mains. A happily less familiar source of public danger, but which may prove to become more frequent as the demands on applied science increase, is, as the experience of the past week would teach, the conveyance of certain chemical commodities along our highways both on land and sea. The bursting of a steel cylinder containing compressed oxygen gas at Fenchurch-street Station on Friday, March 15th, by which a man in charge of it lost his life, cannot be easily accounted for. Why the cylinder up to that moment had successfully resisted the enormous internal pressure of 1800 lb. per square inch, and nearly double that amount if in the ordinary course it had been properly tested before charging, is the mystery which surrounds that unfortunate occurrence. It can hardly be supposed that the cylinder contained an explosive mixture of hydrogen (or coal gas) and oxygen, for example, since the heat developed at the time of charging would probably have been sufficient to cause a powerful explosion. Again, there would appear to be no evidence that the cylinder was submitted to any shock; and, indeed, there is no reason to believe that even if that had been the case the cylinder would have sustained any injury. A properly constructed and tested cylinder is known by experiment to be free from the danger of bursting through being dropped, even from a height of thirty feet and upwards. The only explanation that remains is that an intra-molecular change had taken place in the steel of the cylinder, so that the metal had gradually returned to a brittle and crystalline condition, which careful re-annealing would have eliminated. We believe that it is the practice of the makers of oxygen gas to anneal the cylinders, not only in the first instance, but afterwards every few years, in order to correct any tendency in the metal to harden and become less ductile in the interval. This seems to us to be, therefore, in the present case the only plausible theory, and, that

being so, it is extremely desirable that some steps should be taken to compel gas-makers to make rigid examination of the cylinders at short intervals, so that, in addition to pressure tests, any physical change—from ductility to brittleness—may be counteracted by an annealing process.

It is remarkable, however, assuming that the disaster was due to bursting merely and not to violent combustion—and in that sense comparable to an ordinary boiler explosion—that the discharge was so far-reaching in its effects as to destroy gas lamps and to blow out the face of the clock at the extreme end of the platform. At the most the cylinder probably did not contain more than 20 cubic feet of gas, but the pressure, be it observed, is generally twenty times greater than in an ordinary steam boiler. Had the accident occurred in more confined limits, as, for example, in a railway carriage or in a lecture room, the loss of life might have been appalling. The disaster arising from the storage of chemicals which happened on March 14th on board a Mediterranean steamer belonging to a French company was of a different but equally serious nature. In this case two fluid chemicals mingled together with the production of a suffocating gas, which resulted in the loss of two lives and serious injuries to four other persons. It appears that the vessel, meeting with very heavy seas on rounding Cape Matapan, was at length struck by a huge wave, which shattered a great number of jars that were stored on the deck, some containing sulphuric and others hydrochloric acid. Apart from the intensely corrosive properties of the mixed acids, which found their way into the sleeping compartments of several of the passengers, the effect of the sulphuric acid mixing with hydrochloric acid would be of course to produce gaseous hydrochloric acid. The expedient of storing chemicals on board ship in close proximity to sleeping apartments cannot be too vigorously condemned, and we trust that a thorough and searching inquiry will be made, and that steps will be taken in future to protect the passengers from such dreadful and avoidable risks. We are apparently living in an age when chemicals have, more or less, become necessities and everyday commodities amongst us. Some time ago we recorded an accident arising from the simultaneous presence of chlorate of potash lozenges and match boxes in the same pocket, and other similar accidents due to chemical reactions on the comparatively small scale of domestic environment have been recorded. It is evident, however, that unless great care be exercised, both on the part of the manufacturers and the public, in dealing with these things they will surely have a forfeit to pay for availing themselves of the mysterious forces locked up in nature which man finds it profitable to release temporarily for his convenience and use. Finally, the increasing employment of chemicals such as compressed gases for public use should, it seems to us, shortly afford subject of special legislation and control.

ROYAL BRITISH NURSES' ASSOCIATION.—The fourth sessional lecture of the season was delivered at 17, Old Cavendish-street, on March 15th before an unusually large audience by Sir Dyce Duckworth, the subject being the Modern Trained Nurse. The chair was taken at 8 P.M. by Mr. Herbert Page. A discussion took place at the conclusion of the lecture on the various points raised of special interest to nurses.

Annotations.

"Ne quid nimis."

THE "SWEATING" SYSTEM APPLIED TO THE MEDICAL PROFESSION.

WE receive from all quarters evidence of a general revolt against modes of medical practice which practically amount to the degradation of the profession and the sweating of medical men. The general revolt of course implies a general evil. In one place the vortex into which all kinds of practice are to be sucked is a medical aid association; in another a club established by a commercial company worked by a layman, who gets so much—perhaps 20 per cent.—on the receipts; in another even the old-fashioned, and in its way honourable, "club" is degraded to wrong uses, and made the medium of meanness to a profession which deserves very different treatment from the working men of Great Britain. Against fair combinations of working men for attaining their own legitimate ends we have not a word to say. They have a right to take this course to procure reasonable wages and reasonable reductions in the price they pay for their prime necessities. Medical attendance is one of these necessities. They are as dependent on this as on food or education. And yet it has a delicacy of character about it which cannot be said to attach to any mere article of trade or to the person who supplies it. It cannot be supplied "in the lump." To be valuable it must be individual to a great extent. The individual patient must be considered, and his relation to the medical adviser should be continuous and individual. All attempts at procuring wholesale medical attendance on crowds are bad for the patient. They are also bad for the medical profession, and the profession has a right to object to them as inconsistent with its own proper conditions of work. It has a right to protest against all terms that would convert it into a mere traffic in drugs and take no cognisance of the fact that its members are not mere retailers of such drugs, but highly educated men, whose responsibility is great and whose judgment is, as a nearly invariable rule, equal to that responsibility. We learn that in Lincoln there is a determination on the part of the profession to resist the abuse of friendly societies, medical aid associations, and the like. We have only two words to say on this subject. The first is to express our hearty approval of the stand made in Lincoln and elsewhere. The second is to impress on medical practitioners there and in other places that victory over these evils depends entirely on themselves. The profession in each place must do its own duty. The General Medical Council has, perhaps unfortunately, resolved after full investigation that the evils are not such as it has power to deal with. After all, the profession must look to itself and to its own dignified and effective action in each particular locality for success. If the older and the younger members of the profession in friendly discussion arrive at clear views as to the real significance of these evils and loyally support each other in resisting them the result will soon be apparent. We cannot believe that either working men or the honorary members of friendly societies will, after due notice, allow these institutions to be used to the detriment of a profession to which they owe so much.

THE QUESTION OF THE COMMUNION CUP.

WHEN the story of the sanitary progress of the present century comes to be written it will be incomplete if it does not lay stress upon the fearlessness with which the reformer waged war against possible sources of infection in places where at a period not so very remote from his own mere

criticism would have been looked upon as little less than sacrilege. A controversy is now being raised in America as to the Communion cup as a source of infection to those sharing in the celebration of this solemn rite. This is not the first time by any means that the dangers which may attend the common use of the chalice in the administration of the Sacrament have been made the object of outspoken comment. With the historical aspects of the case we do not profess to concern ourselves, and with the religious aspects we also do not desire to deal. We shall not be suspected of neglecting the latter or of being callous to the great pain that even the idea that the Communion cup could be a source of danger will give to many if we speak only from a sanitary point of view. The administration of the wine to communicants in separate vessels for each would certainly remove a possible source of danger, and to advise this must seem to the ardent hygienist a counsel of perfection. There is, and it cannot be gainsaid, a possibility of infection in the use of the common chalice, and Moses, that prince of health officers, would probably not have sanctioned our present ritual; but, on the other hand, there seems to be no actually proven example of any serious amount of infection being traced to the use of the common chalice, and the precaution, which should give no offence to anyone, of wiping the rim of the chalice with a napkin after each communicant has placed it to his lips should go far to remove what danger there may be. It should surely be unnecessary for us to urge upon those who have only lately entered upon convalescence from some infectious disease the necessity of refraining from publicly taking the Sacrament until a reasonable period after recovery. Human nature, however, is not only weak, but, alas, thoughtless, and a word of warning is not, we think, likely either to do any harm or to give any offence.

THE INTERVIEWER AND THE MEDICAL MAN.

THE custom of interviewing is growing in this country, and there is no doubt a demand for this kind of information, albeit it must often be of the most meagre and occasionally, perhaps, of the least accurate kind. We are led to this consideration by the perusal, in the columns of a Sunday journal, of the report of an interview with a medical authority on the subject of vaccination. Assuming—as it appears to do—that the report gives an accurate statement of that gentleman's views, we may venture to doubt the advisability of these being promulgated in this form. In the main the opinions he is reported to hold are sensible, straightforward, and justifiable inferences from the facts of the case for vaccination; and it is eminently desirable that they should be brought into prominence. But the subject of the manner in which vaccination is performed, and that of its alleged injurious effects, is hardly one to be treated *ex cathedra*, and cannot but open the door to much unprofitable controversy when dealt with so summarily. Amongst the various aspects of the question submitted to the Royal Commission—which has at length resumed its sittings for the purpose of considering its report—there is none which has been more carefully inquired into than this; and we do not doubt that the consideration of the avoidance of all risks as well as the safeguarding of the efficient performance of vaccination will take a prominent place in the long anticipated recommendations that may be made by the Commission. The misfortune of this whole question of vaccination is that it has opened the door to the discussion of strictly technical topics in pathology and therapeutics by those who have had no scientific training and are unable to appreciate the value of scientific evidence. The art of the interviewer is to seize on questions of the day and to give the opinions of experts upon them in a form capable of being

understood by the people; and, seeing how common is the curiosity about medical matters, it is not surprising, although it is none the less regrettable, that the "medical interview" is growing in favour and extent. As medical questions are seldom simple—indeed, often most complex—there can be no two opinions upon the inutility and harmfulness of the practice.

AN ANATOMICAL CURIOSITY.

DR. J. W. OGLE has recorded in the twenty-ninth volume of the *Journal of Anatomy and Physiology* an interesting example in which one of the roots of the left hypoglossal nerve passed through the left vertebral artery within the skull. An excellent drawing is reproduced, but the specimen itself was not preserved. We had almost thought, with Dr. Ogle, that the observation might have been a unique one, for although nerves passing through bones in early development (as, for instance, one of the supra-clavicular nerves passing through the clavicle) are well recognised, nerves passing through bloodvessels, especially arteries, are very rare. Instances are known of the internal anterior thoracic nerve passing through the axillary vein and of the nerves at the bend of the elbow passing through one of the veins at that point; and the nerves passing into the thorax occasionally obtain a passage through the large venous trunks. It is therefore very remarkable that the only other instance of the passage of a nerve through an artery that we can find recorded is by Otto, who mentions a wax model in the anatomical museum of the Joseph-Academie in Vienna, where the hypoglossal nerve also ran through the vertebral artery. The same nerve and the same artery are involved, and it is very curious that such an anomalous development should apparently be thus limited.

METROPOLITAN DISTRICT RAILWAY FARES.

A DISCUSSION which has naturally awakened considerable interest among Londoners has recently arisen concerning some of the fares charged by the Metropolitan District Railway Company. It is alleged that the company has made a practice of charging rates in excess of the limits imposed by the statute under which it carries on its operations, and aggrieved passengers have very naturally made the charge the subject of complaint. We should have supposed that any such infraction of the law would easily be restrained by the Railway Commissioners if the point were proved, and in such a case it is very odd that any serious difficulty should exist about invoking their intervention or placing before them the necessary statement of the case. But however that may be, there are broader considerations to be taken into account in forming an opinion upon the merits of a controversy such as this than the mere letter of a statute thirty years old. The enormous growth of the traffic in the heart of London and of the residential districts on its borders which has taken place during the last quarter of a century may well be supposed to have revolutionised the conditions under which the transport services in all their various departments are carried on. It is difficult to imagine that the scale of charges fixed in the sixties would now need revision in such a sense as to augment the revenues of a railway company circumstanced as is the Metropolitan District; but on the other hand the change of fashions in the matter of class accommodation has been such that it may well have become desirable to readjust the various rates *inter se*. People who thirty years ago would have considered a first-class ticket indispensable to their self-respect may be found to-day very complacently sharing the improved third-class carriage with their less pretentious neighbours. Things like these have a money value when they are regarded from the point

of view of the railway manager, and it would be well both for the critics of the companies and their champions to bear in mind that the terms under which such a service as that which a great railway company supplies is to be undertaken and conducted must in the nature of things be subject to frequent revision, although invested for the moment with the sanctity of the law by Act of Parliament.

COUNTY HOSPITALS AND THEIR MEDICAL STAFFS.

THE question to which attention was directed in our columns last week by Mr. Henry Taylor is one of no small interest to the medical profession in county towns. We may say at once that we fully concur with Mr. Taylor in the views he expressed, although they are contrary to the action taken by the governors of the Surrey County Hospital. It is clearly absurd to contend that, as the hospital is a "county" one, therefore its medical staff should be drawn from other towns than that in which the institution is situated. That the staff appointments should be regulated by the subscription list of residents in various parts of the county is absurd, unless those thus appointed be merely consulting rather than acting medical officers. Apart from the practical inconvenience arising from medical officers living at a distance from the sphere of their hospital work, the general introduction of this principle of selection would, as Mr. Taylor shows, be quite impracticable. Guildford is the county town, not Godalming; and naturally, therefore, Guildford is the seat of the county hospital. It is not claimed that Godalming is ill-served by the hospital; and that its medical men feel a grievance at not having the hospital appointments, which form one of the compensations of a practice in a country town, is surely not the case. The idea probably arose in the minds of some of the influential and active governors dwelling in the charming neighbourhood of Godalming, who, perchance from their attachment to the place, have lost sight of the fact that, after all, Godalming is not Guildford.

INSTANTANEOUS SURGICAL ASSISTANCE.

UNDER this title Dr. Marcel Baudouin has published an interesting report of the plans which he has drawn up for providing the best possible aid at the shortest possible notice at the coming Exhibition of 1900 in France. The necessity of such organised assistance has been shown over and over again by the numbers of accidents which occur in all large exhibitions, both during the building of an exhibition and while it is open. At the Chicago Exhibition the daily number of cases requiring medical or surgical treatment was very great, and on two special days—viz., Oct. 21st and 22nd, 1893—no fewer than eighty-one cases required attendance in one form or another, and the experience gained at Chicago has helped Dr. Baudouin in the formation of his plans for future services. A hospital is to be built in the grounds, and from this as a centre outlying posts are to work. It is proposed to have ambulances stationed in different parts of the exhibition, which can at once be called to any locality by means of telephonic arrangements distributed over different parts, just as fire-engines in London are summoned to a fire. By this means any part of the exhibition can at once get an ambulance, and the injured be given "first aid" and then taken to the hospital. The hospital is to be built in as an advantageous position as possible for receiving patients from any part of the exhibition, and will thus form the centre of the whole system. It is to contain twenty beds, distributed over ten rooms, each room containing two. Four of these rooms are to be given up to surgical beds (two male and two female) and four to medical, while the two remaining ones are to be, if possible, rather larger than the others, and reserved for obstetric and gynaecological cases and for any young children whom it may be desirable not to put in the adult wards, and for this purpose each of these rooms is to

contain a cot in addition to the other beds. An operating room, with adjoining anæsthetic room, is to be built, and is to contain every modern surgical appliance, and there are also to be well-ordered rooms for receiving cases when they first come in. The medical and surgical staff is to consist of a resident surgeon, in command of the service, one non-resident assistant-surgeon, and one non-resident assistant-physician. In addition to these, there will reside in the hospital an assistant in medicine (also a bacteriologist), two surgical assistants, and a dispenser. There is also to be an efficient nursing and domestic staff in the building. It is proposed to raise the necessary funds by taxing the employers of labour according to the value of the constructions they erect in the exhibition, the necessary taxation being estimated at about 5 fr. per 1000 fr. Such a complete system for saving life and limbs will necessarily be an advantage to large employers who are responsible for the lives of the men they employ, as well as to the injured themselves, and it is to be hoped that the authorities will see their way to carry out Dr. Baudouin's carefully worked-out scheme.

SANITARY INSPECTORS AND TENURE OF OFFICE.

A DEPUTATION of the Sanitary Inspectors' Association was introduced on Friday last, by their President, to Sir Walter Foster, M.P., Parliamentary Secretary to the Local Government Board. A full report of the meeting will be found in another column, but we may here note that the deputation, which was very numerous, had for its object the task of bringing before the Secretary the question of the tenure of office held by the inspectors. Their President, Sir Benjamin Ward Richardson, urged that at present sanitary duties could not be properly performed by inspectors unless they were preserved from the danger of dismissal if they independently and faithfully fulfilled their duties in the removal of flagrant causes of disease. He gave an instance in which an able sanitary inspector, who had been for thirty years engaged in the work of inspection, had been peremptorily removed from his duties and left unprovided for, owing to the circumstance that the district in which he had laboured so long had been divided by the county council and that new inspectors were introduced, leaving him altogether unprovided for, without a pension or provision for the future; so it sometimes happens that the man who is most useful is in the most dangerous position of all. Several sanitary inspectors supported their President by details of facts which they themselves had directly observed, and Sir Walter Foster, in his very practical and excellent speech, spoke strongly in their favour and in the direction of their views. He did not admit that sanitation could not be carried on with considerable effect under existing conditions; and he pointed out a series of facts showing that an improved sanitation has led greatly of late years to the reduction of disease. This, he said, was specially marked in regard to the suppression of cholera in this kingdom. He referred to the epidemics of the disease between 1832 and the last epidemic which has appeared, showing that there had been a proportionate decrease of mortality and of cases affected according to the increase and spread of sanitary principles and practice. On the last occasion, in fact, cholera, after being introduced into this country, had been stamped out with a facility which could scarcely have been expected, and which could not have occurred in any other country where the sanitation was less perfect. At the same time sanitation still admitted of improvement, and the fixity of the tenure of office of sanitary inspectors, with an increase of salary for their services, would without any doubt tend largely to this end. Unfortunately there was at this time no Act of Parliament which permitted of such tenure, and he could hold out no hope

that this session there would be any legislation that would bring about what was asked for; but if at any time such legislation were attempted he would bear in mind the request in the most favourable manner he could. Meantime, he trusted that county councillors themselves, who had taken upon themselves the task of local self-government, would be wise enough to lead the way to the necessary reform by improving the salaries and making safer, and therefore more useful, the term of office amongst those who were so willing to serve them in the performance of what was often a delicate and hazardous duty.

APHTHOUS FEVER.

SOME alarm seems to have been caused in this country by a report from Berlin that "a new epidemic" has manifested itself in the south-western parts of that city, of which blisters in the mouth are the most characteristic feature. It is also stated that Professor Virchow regards the malady as the human form of bovine foot-and-mouth disease, induced by consuming the milk of affected cows. There is nothing at all surprising in this occurrence, as the aphthous or eczematous fever of animals known as foot-and-mouth disease is communicable to mankind, chiefly through the ingestion of uncooked milk from cows whose mammary glands are involved in the eruption. Innumerable instances of this transmission, experimental as well as accidental, are on record, and many have happened in this country when the disorder was prevalent, which it was for nearly half a century. Now, however, we are happily free from it, and it is not likely we shall ever see much of it again so long as we keep a sharp look with regard to the importation of cattle. On the Continent it is constantly present in some region or other, and at times is universally prevalent, so that it is not at all startling or wonderful to hear of people suffering from it when no precautions are adopted to render the milk innocuous.

DEATH UNDER CHLOROFORM.

WE are indebted to the house surgeon of the Royal Victoria Hospital, Bournemouth, for the substance of the following account of a death under chloroform. The patient, a man aged forty-three years, was admitted into hospital suffering from a transverse fracture of the patella during November of 1894. On admission his general health was fair, although there was unduly marked arcus senilis, and a history of intemperate habits. The patella was cut down upon and united by wiring. On this occasion chloroform was given from a Skinner's mask, upon which the anæsthetic was sprinkled from a graduated drop bottle. The stage of excitement was unusually pronounced. The inhalation took over ninety minutes, and twelve drachms were used. No unusual symptoms occurred. Recovery was not delayed, and only slight sickness followed. On Jan. 4th, 1895, a further procedure became necessary to remove the wires, and chloroform was again given, a Skinner's mask and drop bottle being employed. About a drachm was sprinkled upon the flannel, when violent struggling took place, the patient raising his head about two feet from the couch. Another drachm was sprinkled upon the flannel and the patient ceased to struggle. He appeared to go under in the ordinary way, his breathing being deep and regular. The corneal reflex was discovered to be absent, and the operation was about to be commenced when the respiration became altered in character, two or three deep, prolonged breaths being taken and then all breathing suddenly ceased. There was neither pallor nor cyanosis. No radial pulse could be felt after the failure of respiration. The usual restorative measures—artificial respiration, injection of ether beneath the skin, depression of the head, and extension of the tongue—were unsuccessfully employed. The necropsy revealed

fatty degeneration of the heart and kidneys. Those present expressed the opinion that death was occasioned by primary heart failure, predisposed to by the diseased condition of that viscus. It is pointed out that the violent struggling which took place during the anaesthetisation probably crippled a heart predisposed to syncopal attacks. There does not appear to be any reason why this patient, who was known to be an alcoholic subject and therefore prone to degenerative changes, should have been given chloroform. During the first operation he struggled, and presumably a like state of things would occur again; under these circumstances we doubt whether chloroform, which was likely to depress the vital processes and place the patient in grave danger, was the best anaesthetic. The preparation, the choice, and the management of the anaesthetic, however, often tax the resources of the most experienced chloroformist and confront the less expert practitioner with a problem the solution of which he may well fail to discover without any blame being incurred by him.

TWO SUPERNUMERARY TESTES.

SUPERNUMERARY testes are notoriously very rare. A case was recently reported to the Clinical Society of London. It is less remarkable than one reported in the *New York Medical Record* of Feb. 23rd. The case was noticed first by Lieutenant Alex. M. Davis, recruiting officer of the Eighth Cavalry, who took it to be a case of one superfluous testicle. On taking the recruit to a physician the latter found him to have four testes. Three were on the left side of the scrotum and one on the right. They were all apparently perfect testicles, and gave the peculiar pain incidental to pressure. Three were large and well developed, and one situated high up in the scrotum was small. There appeared to be but two spermatic cords, though the two large testicles on the left side seemed to be connected by a subsidiary spermatic cord.

BISKRA.

In the *Fortnightly Review* Major Arthur Griffiths gives some interesting information regarding a health resort to which we have more than once referred in our columns, but about which there is little accurate or precise knowledge. The place in question is Biskra, situated in an oasis beyond the Algerian mountains, and on the verge of the Sahara. Major Griffiths is disposed to think that the attractions and virtues of Biskra have been unduly magnified, but, in spite of some drawbacks, he gives a verdict of qualified approval. He writes from personal knowledge and from recent experience. The two special advantages of Biskra are "climate and comparative propinquity." As regards climate, Sir Lambert Playfair, a competent authority, says: "The climate of Biskra is delightful during six months of the year. Nowhere in Algeria can we find a more genial temperature, a clearer sky, or more beautiful vegetation. It is practically rainless; the only drawback is the prevalence of high winds." Other authorities speak in even stronger terms, and it is claimed for Biskra that it is comparatively free from that chill at sundown which is the bugbear of so many otherwise fine climates. The winds, however, would appear to be a serious drawback. They are often very tempestuous, blowing almost with the force of a tropical typhoon, and when they come from the north and pass over the snow-capped Atlas Mountains they are apt to be bitterly cold. The storms at Biskra differ in one important respect from those of Egypt—viz., they do not raise the vast quantities of dust familiar to the traveller on the Nile, the reason being that the desert surrounding the oasis is mainly hard and stony. The hotels and houses at Biskra, being built with a view to protection against heat, are not well adapted to withstand these storms and are very draughty during their continuance. Still, the

air is very fine; it is "dry, often warm, always invigorating, with a certain fine champagne-like quality of briskness, which, without being too stimulating or exciting, makes it delightful simply to breathe." As regards propinquity to England, Biskra has a considerable advantage over the resort most analogous to it in point of climate—viz., Upper Egypt. "The railway journey to Marseilles is the same in both cases; then four days remain for the sea voyage to Alexandria, against twenty-six to twenty-eight hours to Algiers, or thirty to Phillipville. Again, the desert of Sahara is certainly much nearer the Algerian seaboard than are Luxor and Assuan, with presumably parallel climates to Alexandria." The journey by rail from Algiers to Biskra is 400 miles, and a night must be spent *en route* at Setif, where the accommodation is described as inferior. From Phillipville the journey is only 200 miles, and can be made in one day, but against this great advantage must be set the serious drawbacks that the Compagnie Transatlantique do not run their best boats to Phillipville and that the hotel accommodation there is only third-rate. On the whole Major Griffiths is inclined to recommend the route *viâ* Algiers. The attractions of Biskra, beyond its admirable climate, do not seem to be numerous or great. The hotels are fairly good, but the *cuisine* suffers from inevitable monotony. There are gardens, a casino, a curious market, a negro village, the baths of Salahin, and neighbouring oases which may be visited. The sportsman, "if he is enterprising and fairly hardy, enough so at least to face the trials of tent-life, will be rewarded by good bags of gazelle, bustards, hares, snipe, and, in the proper season, quail." The supply of horses is not very good, and the prices demanded are often extortionate. In the matter of antiquarian remains, although Algeria is far behind Egypt, it is nevertheless very interesting. "At no great distance from Biskra are the famous Roman ruins of Thimegad, the ancient Thamgas, second only to those of Pompeii, and in excellent preservation. Near it is Lambessa, the city of the third Augustan legion, another Roman remain which would well repay the visitor, but neither Thimegad nor Lambessa can be approached without great pains and fatigue, with a night's lodging at the indifferent hotel of Batna thrown in."

THE CARDIAC PLEXUS IN DIPHTHERITIC PARALYSIS.

In the *Archives de Médecine Expérimentale et d'Anatomie Pathologique* Dr. A. Vincent has written a paper in which he strongly controverts the current view that in convalescence from diphtheria myocarditis is the only condition which leads to cardiac failure. Another view, that this condition is the result of an affection of the vagus or sympathetic, is not favoured by the exceedingly slight changes which are found in those nerves. The myocarditic theory, on the other hand, is contradicted by various observations in cases of patients dying in the course of convalescence from diphtheria in which no affection of the heart muscle was present. Dr. Vincent quotes such a case, which he had himself observed and examined, and he expresses the opinion that the reason why the cardiac failure has not been ascribed to its true cause is because only the nerve trunks have been examined, while the state of the cardiac plexus has been overlooked. In confirmation of the importance of carefully examining this he quotes the case of a man who died from cardiac failure after diphtheria, and in whom a careful examination of the medulla, spinal cord, and vagus and sympathetic revealed no abnormality. In the plexus cardiaco-aortic, however, there were widespread parenchymatous changes differing in degree in different parts, while in the muscle fibres of the heart the transverse striæ were well retained as a rule, and only in a few were they indistinct or absent. In the cardiac plexus also similar changes to those above described

were found—i.e., changes exactly analogous to those found in the peripheral nerves in post-diphtheritic paralysis. Dr. Vincent accounts for the fact that the trunk of the vagus was not affected by supposing that the course of the disease was so rapid that death ensued before the changes in the trunk of the vagus could manifest themselves. The changes in the plexus were severe and quite out of proportion to the affection of the myocardium, and there could be little doubt that the former were the cause of death. This observation of Dr. Vincent, together with one by Dr. P. Meyer, are said to be the only ones in which the cardiac plexuses have been examined; but the very definite changes described by both observers make it desirable that future observations should be directed to the elucidation of this point.

DEPRIVATION OF DEGREES.

THERE is good reason to hope that universities will soon acquire a similar power to that possessed by corporations of expunging the names of those of their members who have been guilty of conduct unworthy of their position. It will be remembered that at its last meeting the subject was brought to the notice of the General Medical Council in a motion by Dr. Glover. The motion was withdrawn after a satisfactory discussion, in which the representatives of universities showed every disposition to consider their duty in this respect. We now understand that the Council of the Senate of the University of Cambridge recommend that the following new statute for the University be made as to the deprivation of degrees—viz.: If the Chancellor of the Sex Viri, or four at least of their number, of whom the Chancellor shall be one, shall report to the Council of the Senate that it has been proved to their satisfaction that a graduate of the University has been convicted of a crime for which he has been sentenced to penal servitude or imprisonment, and that such crime is one which renders him unfit to be a member of the University, that the Council of the Senate may propose to the Senate a grace depriving him of his degree or degrees, and of all privileges enjoyed by him as a member of the University, and in case the grace be approved by the Senate he shall be deprived accordingly. The Convocation of the University of Durham has lately ordered the removal from the calendar of the University of the name of one of its medical graduates who had been found guilty of felony.

THE CORONER FOR CHESHIRE.

MR. HENRY CHURTON, the medical coroner for the division of Cheshire which includes Birkenhead, is the premier coroner for England and Wales, having celebrated his jubilee as coroner several years ago. He fought a most plucky fight against his legal opponent, and was successful. During his long career many changes have occurred, involving increased duties, and Mr. Churton accomplished all these with credit to himself and advantage to the community. Though past four score years, Mr. Churton possesses excellent health and has a commanding presence. It is all the more to be regretted, therefore, that he should bring a prejudice to his profession and office by an excessive irritability of temper. Not long ago he was taken to task by Mr. Justice Wills in the Crewe murder case, in which two youths were charged with the murder of their father. For very cogent reasons the police authorities declined to produce the prisoners at the inquest, which so ruffled the coroner, who evidently regarded it as a slight upon himself, that he sent no depositions to the trial, a proceeding which was condemned by Mr. Justice Wills and was noticed in THE LANCET at the time. More recently he acted with discourtesy at an inquest he held at the Clatterbridge workhouse. The jury had walked

a considerable distance, and, the weather being extremely inclement, naturally asked if they might be allowed the use of a conveyance or conveyances home. Without any expression of sympathy he sharply intimated that he could do nothing for them, and that they must find their way home as well as they could. In another case he was discourteous to a solicitor who represented the Society for the Prevention of Cruelty to Children at an inquest on the body of a child who had died presumably from neglect. In the third case he made such an attack on Dr. Monro, the house surgeon of the Wirral Hospital and Dispensary for Sick Children, that the chairman of the acting committee addressed a letter to the editor of the *Liverpool Daily Post*, in which he proceeded to show that the coroner was himself remiss in not communicating with Dr. Monro and summoning him to the inquest. There is another matter which ought to be noticed. Birkenhead is now a large incorporated town rapidly rising in population—already over 100,000—and in importance. It ought to have its own borough coroner and not remain any longer in the county coroner's district, such an arrangement being the cause of much delay in the holding of inquests and other inconveniences.

THE PSYCHOLOGY OF ANÆSTHESIA.

IN the course of an interesting letter, which we print elsewhere, Dr. Wyld calls attention to the phenomena of mind during partial anæsthesia. While we cannot quite accept as feasible his suggestion that experimental psychology should be studied from evidence derived *quâ* narcosis, we recognise a peculiar interest in the study of such dreams. Dr. Wyld's visions are not singular. He himself draws attention to the frequency with which persons experience such exiliatory phantasms under chloroform and other anæsthetics; and in the "Life of John Addington Symonds" we read: "On Tuesday I was put under the influence of chloroform and laughing gas together" (*sic*). He then details his vision. "I seemed at first in a state of utter blankness; then came flashes of intense light alternating with blackness, and with a keen vision of what was going on in the room round me, but no sensation of touch. I thought that I was near death, when suddenly my soul became aware of God, who was manifestly dealing with me, handling me, so to speak, in an intense personal present reality. I felt Him streaming in like light upon me and heard Him saying in no language, but as hands touch hands and communicate sensation, 'I led thee, I guided thee; you will never sin and weep and wail in madness any more; for now you have seen Me.' My whole consciousness seemed brought into one point of absolute conviction; the independence of my mind from my body was proved by the phenomena of this acute sensibility to spiritual facts, this utter deadness of the senses; Life and Death seemed mere names....." Symonds adds, "I cannot describe the ecstasy I felt," and referring to his experience and its psychological evidence, says, "If this had happened to a man in an uncritical age would it not have carried conviction, like that of Saul of Tarsus, to his soul?" There is no doubt, as has been pointed out, that these visions are the product of that kind of enhanced idea formation which occurs as the patient is "going over." At this time the senses are abnormally acute, but the impressions they convey are not true presentments of the physical stimulus received. They partake of the nature of hallucinations. Of course, the anæsthetics now in use are by no means the only drugs giving rise to dreams of elation. Hashish and the more familiar alcohol give psychological evidence of a like character. De Quincey, writing of opium in his "Confessions," sums up the action of alcohol as against his favourite nepenthe: "A man who is inebriated, or tending to inebriation, is, and feels that he is, in

a condition which calls up into supremacy the merely human, too often the brutal, part of his nature; but the opium eater feels that the diviner part of his nature is paramount—that is, the moral affections are in a state of cloudless serenity, and high over all the great light of the intellect." In a similar strain have the victims of cocaine told of its wonderful dreams and soul-stirring visions. The circulatory changes in the nervous system which bring about ordinary dreams in an undrugged person, and the morbid conditions of the nervous system which evolve vision seers and Lourdes miracles, are probably but variants from the states called into existence by the physiological effects of anæsthetics and narcotics—

"How sweet it were, hearing the downward stream,
With half-shut eyes ever to seem
Falling asleep in a half dream!"

ASEPSIS IN CATHETERISM.

A RECENT number of *Przegląd Chirurgiczny*, the Polish surgical review, is largely taken up by Dr. S. Groszlik's article upon Asepsis in Catheterism. Reviewing the methods usually employed for sterilising catheters and bougies, he finds most of them to be unsatisfactory. Bacteriological experiments made by himself showed that neither mechanical cleansing nor the use of liquid antiseptics, sulphurous acid gas or mercurial vapours thoroughly sterilised instruments which had been artificially infected with cultivations of staphylococci and streptococci. This end can only, he affirms, be gained by employing moist heat. Dr. Groszlik describes fully an apparatus, apparently simple and effective, which he has devised for this purpose. In this the instruments are sterilised in five minutes. Elastic instruments, it may be noted, are declared to be unaltered by the process. A useful bibliography is appended to this article.

COUNTRY HOLIDAYS FOR FACTORY GIRLS.

OUR readers will remember Captain Morris's cynical summary of the delights and wearisomeness of the country, but then he lived in Pall Mall, within easy reach of the green trees, ducks, and water of St. James's Park, and there are people in London, who do not live in Pall Mall, to whom the prospect of a visit to the country represents wonders unknown and pleasure untold. It is a physiological maxim that the constant use of one function, if performed voluntarily, will in time produce degeneration of the organs to which that function belongs, and the London factory girl in her daily work is much exposed to this danger. She stands or sits all day in her "shop," and in most cases feeds a machine—an insatiable monster like the daughter of the horse-leech, for ever crying "Give, give," which, whether it be fed with soap, envelopes, sweetmeats, or leather, is always ready for more. Conceive then the rest to the wearied brain and the tired muscles of a week in the country with nothing to do, away from the smoke and the noise of the crowded town, to lie on some warm hillside when the breeze blows off the Surrey heathlands, or, greatest treat of all, perhaps, to see the sea at some place other than Southend on a Bank Holiday. The factory girl is known to most of us only as a person who wears boots with brass eyelets and red laces, an enormous hat with three ostrich feathers dyed in aggressively brilliant secondary aniline colours, and a long black cotton velvet mantle. She is also a lady of unfettered speech and prone to acts which would horrify Mrs. Lynn Linton. But with all this "Lizerunt" and her companions have a great deal of sterling worth in them, and these good qualities are marvelously brought out by the assistance of the excellent society for whom we now plead. The Factory Girls' Country Holiday Fund was started by Miss Canney in 1888, and from its last report which we have just received, we find that by its agency 704 girls and women were sent into the country for

periods varying from a week to a fortnight. The average cost is 10s. a week and most girls pay a part at least of this. Subscriptions may be sent and will be most gratefully acknowledged by Miss Canney, St. Peter's Rectory, Saffron-hill, E.C., and we commend this work very warmly to our readers.

BLACKMAILING.

THE Wisbech borough magistrates have had before them a charge against Mr. George Bury of Wisbech, house surgeon of the cottage hospital, of assaulting one Fanny Maud Lillian Johnson. The examination was very damaging to the complainant, and the case was dismissed after a very brief consultation. Mr. Bury is to be congratulated, not on the dismissal of the case, which never assumed a serious aspect as far as he was concerned, but on the manly way in which he met the charge. A medical man deserves the thanks of the profession and of all respectable people for exposing such a case.

HEMIPLEGIA WITHOUT BRAIN CHANGE.

Dr. JACOBSON of Copenhagen has an interesting paper on this subject in the *Deutsche Zeitschrift für Nervenheilkunde*, of which an abstract appears in the last number of the *Neurologisches Centralblatt*. He has himself observed six patients in whom, clinically, the usual symptoms of a typical apoplectic attack were present, but careful examination of the brain failed to reveal any lesion except widespread arterial sclerosis. He also collected the records of thirty-two other cases described by various writers, and by a comparison of these with his own cases he finds that the hemiplegia in those patients manifests itself during an illness of some kind, most frequently during uræmia, but also during phthisis, or after pneumonia, lead-poisoning, or puerperal fever. The hemiplegia present is in all respects the same as that associated with a definite focal lesion and is usually fatal soon after its onset. Dr. Jacobson believes that in these cases the hemiplegia depends upon some circulatory disturbance, determined possibly by some inequality of pressure on the two sides of the brain, and that the cases usually end fatally because of the advanced age of the patients and the arterial sclerosis which is present, assisted perhaps by the toxic condition.

THE PRUDENTIAL ASSURANCE COMPANY.

THE magnitude of the operations conducted by the Prudential Assurance Company has long been matter of common remark, and, indeed, the figures annually reported are such as to strike even the most casual observer. With a revenue which aggregates upwards of six and a quarter millions sterling this great institution cannot but be conspicuous, and if conspicuous impressive. But the real significance of these astonishing figures can only be appreciated when it is borne in mind that the great total is produced by the collection of a vast number of contributions which are individually small. Upwards of two-thirds of the whole income is brought to account in the industrial branch—that is to say, represents the thrift of labourers and artisans and the "working classes" generally—and is contributed in weekly pence. Even the premiums which are paid in what is for distinction called the ordinary branch, and which amount in the whole to more than £2,000,000 per annum, even these are for the most part received in comparatively small sums. The Prudential is characteristically a poor man's life assurance company, and for this reason its prosperity is a matter of the very greatest public concern. The extent of its ramification through the humbler ranks of British society will be a matter of no surprise to the majority of our professional readers, being, indeed, pretty constantly brought to their notice in

the ordinary course of practice. But it is on that account the more interesting to us to be able to gather from the report and statement of accounts recently published and circulated that the society continues to enjoy marked prosperity. Nor is "prosperity" in this instance a mere synonym for "popularity." An annual valuation, made on the most approved principles by actuaries of the highest reputation, affords a guarantee for the continuance of this prosperity, with which not only may the members of the society be well content, but which is matter for satisfaction to the public at large, seeing that the scale and character of the task which the directors of this society have undertaken are such as to render its permanent success a matter of national importance.

VACCINATION AND SMALL-POX AT WILLENHALL.

A VERY interesting account of the outbreak of small-pox which occurred in this district during 1894 is given by Mr. John T. Hartill in his annual report. There were in all 842 cases of the disease, 588 being treated at home and 254 in the hospital. The history of 830 cases was traced, and their condition as regards vaccination and small-pox was as follows. Out of 89 which had never been vaccinated no less than 30 paid the full penalty of their own or their parents' neglect of the Vaccination Acts and died; while among 739 cases which at some time or another had undergone vaccination there were but 17 deaths. The remaining 2 cases had had a previous attack of small-pox, but had never been vaccinated. It is thus seen that the death-rate among the unvaccinated was 33·7 per cent. and among the vaccinated 2·3 per cent., or, put another way, the death-rate among the unvaccinated was fourteen times and a half greater than among the vaccinated. Furthermore, it was found that the death-rate among the vaccinated ranged from 4·1 per cent. in those with but one scar to 1·0 per cent. in those with four scars, whilst it was *nil* among the revaccinated. In regard to severity of attack it seems that amongst the unvaccinated the severe cases amounted to 95·5 per cent., as against 26·6 per cent. among the vaccinated. Mr. Hartill supplies other interesting information in regard to the preventive and modifying value of vaccination, and we commend his very lucid account to all those who are prepared to read it in an unbiased spirit.

THE LONDON AND MANCHESTER INDUSTRIAL ASSURANCE COMPANY, LIMITED.

WE have been invited in two quarters to express an opinion upon the society and its working. To be thrifty at one's own expense is praiseworthy, to be so at the expense of another to some perhaps would seem to be still better. The London and Manchester Industrial Assurance Company, Limited, offer to their clients the following advantages: 1. A certain sum at death, varying according to the date of death and the amount of the weekly premium. This, it must be owned, is a very excellent arrangement. 2. Medical attendance and medicine in illness. The medical referee, we observe, signs a paper on appointment, wherein he agrees to examine candidates and sign a certificate, for which he will receive a certain fee—i.e., when the sum assured is under £25 he receives 1s.; between £25 and £50, 2s. 6d., and so on. In addition he agrees "for the under-mentioned consideration to give and supply at all times when required attendance, medicine, and advice to the best of my judgment to one and all of the said members residing in this district that become my patients the said members to pay for leeches when needed and find their own bottles or be charged extra for the same if found by me. The sum of 10d. per member per quarter to be paid by the company for all members whose names appear upon the list be they few or many." Thus for 3s. 6d. per annum every member gets

medical advice, presumably skilled, and medicine, but not leeches! Now, let us compare the internal economy of a house with that of the body. The house doctor is the plumber and gasfitter. Imagine an association formed whereby a plumber should be induced to sign an agreement that for the sum of 3s. 6d. per house per annum he would attend whenever he was required to see that there was nothing wrong with the pipes, he himself supplying piping, solder, pumps, gas burners, &c. The inevitable candle required would be supplied by the patient—we mean householder. This would be an exactly analogous condition of things, except that leeches are required less frequently than candles. Provident dispensaries are all very well, being in the nature of charity, but for a big commercial undertaking to make profits out of the sweating of medical men who voluntarily sell themselves into bondage is not consistent with either professional opinion or English ideas of fair play. It will be noticed that the estimate of one of our correspondents whose letter is published in another column—i.e., 2d. a week—is too high; 10d. for thirteen weeks is a fraction of a penny per week. The system of touting which he mentions is much to be deprecated, and we must say that, in our opinion, medical men would be wise to dissociate themselves from a society which pursues such methods.

THE BACTERIOLOGY OF GRAVEYARD SOIL.

DR. JAMES BUCHANAN YOUNG, in a paper read before the Royal Society of Edinburgh last year, and which he has now reprinted in pamphlet form, gives the results of some experiments undertaken by him on the chemical and bacteriological condition of soil, with special reference to the soil of graveyards. Samples of soil for bacteriological examination were taken with all due precautions from graves which were being opened for burial, and the examination was made with as little delay as possible. Without describing the methods adopted by Dr. Young or enumerating the organisms discovered, we may indicate here the general results which were arrived at. Dr. Young concludes that the soil of graveyards contains, as a rule, more bacteria than virgin soil; that the bacteria are not most numerous immediately surrounding the coffins, but at some distance above, and that at a short distance under the coffins there is a marked diminution in the number of bacteria present. In the immediate vicinity of the coffins the liquefying bacteria (*proteus vulgaris*) especially were very abundant. Finally Dr. Young points out that so far as his experiments have gone they tend to show that burial has little, if any, effect in increasing the organic matter in the upper layers of the soil, whereas it has a marked effect on the layers containing the coffins—i.e., at depths greater than four feet or thereabouts from the surface. The organic nitrogen and carbon in graveyard soil are, Dr. Young remarks, by no means so great in amount as is commonly supposed, and he considers that if burial is properly conducted in suitable soil there need be no risk to the health of communities.

COLOUR VISION AND ACCIDENTS.

IN our issue of March 2nd we published a letter from Dr. Gowers asking a most pertinent question—viz., "Has any accident been brought home to defect in colour vision?" To this question no answers have as yet been received, and this is all the more surprising as of late great attention has been paid to the subject. Mr. W. M. Beaumont in our issue of Feb. 9th, 1895, instanced the case of a railway guard who was incapable of distinguishing between red and green, and Dr. W. C. Rockliffe, in our issue of Feb. 23rd, gave a number of instances of colour blindness occurring in the mercantile marine. The deputation of ophthalmic surgeons which waited on Mr. Bryce upon Feb. 1st, and which was exhaustively commented upon

in our leading columns upon Feb. 9th, will be fresh in every one's mind. Thus the existence of colour blindness is an absolute fact, but does it necessarily follow that because a man picks out a grey wool when told to select a green, or an emerald green when told to select a rose, that he cannot tell that there is a difference between a red and a green light, or be conscious which light is shown. Dr. Gowers's desire for information derives additional pertinence from Dr. Rockliffe's paper. In this, it will be remembered, some cases were described of men who were rejected as captains on the score of defective colour-vision, having passed a presumably careful examination for colour-vision for the post of mate. It is important to know the details of the failure which entailed rejection, and also the power of adequate discrimination of red and green lights these men possessed. The point raised is urgent, and the question should be answered without delay. It is all for the benefit of railway and steamship companies that any element of doubt as to the capability of their servants to conduct traffic safely should be set aside, while common justice makes it necessary that rejections should not be capricious or unnecessary. Perhaps a Departmental Committee might be appointed to set this matter at rest.

THE HEALTH OF LORD ROSEBERY.

LORD ROSEBERY continues to suffer very much from sleeplessness, and this is aggravated by any attempt to attend to public business. While at the Durdans he has been out for drives on the Downs to Boxhill and other places in the neighbourhood daily, and has taken short walks in addition, but neither the air nor exercise has proved quite efficacious. Certainly some of the reports of the Premier's condition have been unduly gloomy. Except when wearied and discouraged by a particularly bad night he is cheerful, and has enjoyed the society of the friends who have in turn visited him at Epsom. His fortitude is really remarkable under one of the most trying and wearying conditions known to medicine. Throughout his illness he has never said an irritable word to anyone, and even when most sleepless he resolutely and quietly throws off any depression which he may feel in the early morning. Lord Dufferin has placed Walmer Castle at Lord Rosebery's disposal, who will probably go there shortly, but not until the insomnia has abated. For the present he is advised that he will be more comfortable in his own house.

THE INFLUENZA EPIDEMIC.

THE present outbreak of influenza seems to be rapidly extending, and to be resembling in its far-reaching spread the visitation of five years ago. Thus it has become extremely prevalent in St. Petersburg, in Christiania, Copenhagen, and Berlin, and on the whole its line of spread has been rather from west to east, than at the period referred to, when it may be remembered its rather uniform advance across Europe from the east, led it to be generally termed "Russian influenza." On this occasion England would almost claim the unenviable position of being the starting point for the pandemic. Especial mention has been made during the past week in local newspapers of its great prevalence in Rochdale, in Cheshire, and in North Wales, but in point of fact there is no doubt that it is widely prevalent in almost all parts of the kingdom. Its ravages in Dublin and Newry are referred to by our correspondents in Ireland. The Registrar-General's returns for the week ending March 16th show a diminution in the number of deaths directly attributed to influenza—349, as compared with 473 in the preceding week; whilst there has also been a decline in the deaths from respiratory diseases—viz., from 1366 to 1031, the latter being, however, in excess of the corrected average by 507. The general

mortality rates of the thirty-three great towns in England and Wales show mostly a diminution as compared with last week, there being only three towns in which the estimated annual death-rate for the week was 40 or more per 1000—viz., Preston, 40; London, 41·2; and Brighton, 48. The exceptionally high rate at the last-named town, exceptional both comparatively and actually, may perhaps be ascribed in part to the immigration of influenza sufferers to this famed resort for convalescents. In the February summary issued by Dr. Seaton, the medical officer to the Surrey County Council, reference is made to the rapid extension of the disease during that month; including an interesting statement by Mr. Child, M.R.C.S., of New Malden, to the effect that, whereas in January there were 89 cases of influenza in a population of 3437, in February there were 461 in the same population—i.e., nearly one-seventh.

THE DIFFERENTIATION OF OBSCURE THROAT DISEASES.

WE learn from some medical officers of health that considerable help has been afforded through them to medical practitioners having cases of doubtful sore-throats to deal with by reason of the system inaugurated by the Local Government Board of having scrapings or other material from such throats submitted to microscopical and cultural examination. The resulting information is at once telegraphed to the health officer concerned. The conditions under which the material must be sent to the medical officer of the Local Government Board are (1) that it should be transmitted by the local medical officer of health; (2) that it should be accompanied by a clinical history of the case; and (3) that when once the disease in question is ascertained to be diphtheria no more cases from the same locality and outbreak shall be submitted, it being then the duty of the local authorities to deal with subsequent cases as diphtheria.

THE Samaritan Fund of the Westminster Hospital is in urgent need of assistance, and an appeal is now being made for help to carry on the work. The almoner of the fund or the secretary of the hospital will be happy to supply information or receive contributions.

THE *Times* of March 21st states that a compulsory winding-up order has been made against the "Medical Electrical Institute (Limited)," which in October, 1894, was formed to take over the business of the Medical Battery Company (Limited).

MR. THOMAS SMITH, senior surgeon to St. Bartholomew's Hospital and a late Vice-President of the Royal College of Surgeons of England, has been appointed Surgeon Extraordinary to the Queen in the room of Sir William S. Savory, Bart., deceased.

MR. HERBERT W. ALLINGHAM, late demonstrator of anatomy at St. George's Hospital, was elected on Monday last to the vacancy on the staff of that institution as assistant surgeon.

HASTINGS AND EAST SUSSEX HOSPITAL.—The annual meeting of this institution was held in the hospital at Hastings on March 12th, the Rev. F. Young presiding. The fifty-fifth annual report was presented, and showed that during the past year there had been 638 in-patients and 3100 out-patients. The total income for the year was £3770 and the expenditure £4126. Under the head of legacies there was an increase of £904, and when these sums were carried to the capital account the result was that the expenditure exceeded the available income by £1355.

Pharmacology and Therapeutics.

PATENT MEDICINES IN AMERICA.

THE movement against the dissemination of nostrums is growing in America. In our issue of March 2nd we commented upon the introduction of a Bill in the Alabama Lower House with reference to their sale. We now learn from the *New York Medical Record* that a Bill has been introduced into the New York State Legislature with the same object; and the *Philadelphia Medical News* says that a Bill is pending before the Legislature of Tennessee to compel all patent medicine manufacturers to publish their formulas. Concerning this the *Chatauque News* protests as follows: "We desire to enter here our most emphatic protest against this measure. It means a loss of hundreds of thousands of dollars to the State. No reputable manufacturer would think of giving away his formulas in this manner so that anyone who chooses could take advantage of the legitimate secrets of his trade. Before they would divulge these secrets they would withdraw entirely from the State. The result would be that the druggists, a large part of whose trade lies in patent medicines, would be deprived of a principal source of their income, the railroads would lose immense amounts of freight, and the newspapers would be almost ruined. The advertisements of patent and proprietary medicines constitute a very large part of every newspaper's business, and many of the country weeklies would have to suspend publication if it were not for this patronage. The day has passed when the best physicians refuse entirely to prescribe these remedies. Most of them find occasion at times to use them in their practice. The really skilful doctor is not injured. The people are not imposed on to any large extent. They soon discover what is fraudulent and what is of genuine merit. The Bill can help no one but physicians who have not the ability to command practice on their own merits, but who hope by this means to compel patients to call on them." "The people are not imposed upon to any large extent." What refreshing candour. The *American Druggist* says that druggists are so no longer, nor are they apothecaries, but "prescription specialists."

FLUORIDE OF SODIUM IN INFANTILE TUBERCULOSIS.

The *Brussels Journal of Medicine, Surgery, and Pharmacology* reports some observations of Bourgois to the following effect. In the course of some experiments in the treatment of pulmonary phthisis by inhalations of hydrofluoric acid he was struck by the following facts. A woman whom he was treating by inhalations used frequently to bring her child with her. This child, who was afflicted with spinal caries, but without any chest lesion, used to sit with its mother in the inhalation chamber, and after some sittings its weight had increased from 14½ kilos to 19 kilos. Other children affected with non-pulmonary tuberculous lesions treated in the same way showed a similar improvement. Bourgois then took to administering fluoride of sodium by the mouth. The cases selected presented various tuberculous troubles—chronic bronchitis, otitis, and conjunctivitis—and all had a tuberculous family history. Under the fluoride treatment they all improved notably—an improvement which has persisted. Bourgois concludes: (1) purified fluoride of sodium has a marked action upon children, whether they only have a tuberculous diathesis or are already tuberculous, and the good results are enduring; (2) the dose is from ½ milligramme to 5 milligrammes a day; (3) when the specific effects of the remedy manifest themselves the dose is lowered; and (4) children take the drug very well and hardly ever show any intolerance.

SULPHATE OF COPPER AS A BLOOD-FORMER.

The *Répertoire de Pharmacie*, quoting from the *Rundschau für Pharmacie*, recommends the use of sulphate of copper as far preferable to iron in anæmia. Cervello, who reports the case, gave it twice a day immediately after food in doses of 2 to 6 centigrammes = ⅓ to 1 grain.

SUGAR AS A UTERINE STIMULANT.

Modern Medicine says that Professor Bossi of the Obstetrical and Gynecological Clinic of Genoa, Italy, has been experimenting with ordinary cane sugar as an oxytocic, and reports that "sugar in doses of one ounce dissolved in eight ounces of

water is an effective oxytocic, acting usually within a half hour after its administration. Usually a single dose is sufficient. In extreme cases a second dose, administered at the end of two hours, was found effective. The advantage claimed for sugar as a stimulant in labour is the fact that it does not produce tetanic contractions and does not cause retention of the placenta. These observations seem to agree with physiological experiments made within the last year or two, which indicate that the ingestion of sugar is followed by immediate and considerable increase in muscular energy.

THE PHYSICIAN'S VADE MECUM.¹

This is an attempt to compress the arts of medicine and therapeutics into an oblong duodecimo of 500 pages, but like all these kind of books it is either too big or too small. Hardly anything is said about spinal nervous disorders except that some half dozen prescriptions are given for paralysis, but in most of them we are not told under what circumstances they are to be used. Thus a prescription containing iodide of potassium is given for lead poisoning, and one so remarkable that we quote it in full. "Potassii iodidi, dr. ii.; ext. ergotæ fluidi, oz. i.; ext. nucl. vomicæ, dr. i.; tincturæ cardamomi co., oz. i.; syrupi, q.s. M.S. Dose, oz. ss., night and morning. (Due to lead poisoning)." If these directions were faithfully carried out the patient's illness would soon be due to other poisons than lead. Imagine starting with a dose of twenty or twenty-five grains of iodide and twelve or fifteen of the extract of nux vomica. "Syrupi, q.s." may mean anything. Some prescriptions are given for heart disease, but little is said about valvular lesions, or in what form some particular prescription is to be employed. The author notes that the composing was done by the Linotype process; this will perhaps account for "Pharangitis," p. 438. The book teems with inaccuracies—e.g., Hippocrates' facies—that of agony. From this, most people who read it would imagine that "Hippocrates' facies" meant that of acute pain, whereas it does nothing of the kind; and from the rest of the work we should be very disinclined to believe that the author used the word "agony" in its strictly theological sense. A little further on we find "Pott's fracture—fracture of the tibia," a most insufficient definition. The author tells us in the preface that "this little volume has been prepared for the busy physician, pharmacist, and medical student a brief examination of its contents will convey a clearer idea of its nature and scope than any statement could do." We cordially agree with him.

THE HYPODERMIC ADMINISTRATION OF ARSENIC IN LEUKÆMIA.

Dr. S. Rummo strongly recommends² arsenic in leukæmia and pseudo-leukæmia, administered hypodermically in the form of arsenite of soda. The ordinary Fowler's solution is painful, not only because of the lavender it contains, but because it is too concentrated. He uses a solution of arsenite of soda of the strength of two grains to the ounce and commences with a dose of one-twenty-seventh of a grain. This dose is gradually increased until, after some fifty injections, have been given, nearly half a grain—forty-five hundredths—is reached. Of course, the patient must be very carefully watched during the whole of the treatment, which must at once be stopped on the appearance of any signs of poisoning. According to Dr. Rummo it is necessary to push the drug until signs of intolerance begin to manifest themselves. He thinks that, given in the way above recommended, it is by far the most satisfactory of all the numerous remedies proposed for leukæmia.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST.—

The eighty-first annual meeting of this charity was held at the hospital in the City-road on March 13th. Mr. Sheriff Hand presiding. During 1894 there were 477 patients admitted, and the attendances of out-patients numbered about 19,000. The drainage system has been entirely renewed and improved at a cost of £2900. The income for the year was £8700, and fell short of the expenditure by nearly £1500, so that a substantial loan had to be obtained from the bankers on account of the exceptional outlay on the drainage works.

THE LOCAL GOVERNMENT BOARD AND THE SANITARY INSPECTORS' ASSOCIATION.

ON Friday, March 15th, Sir Walter Foster, Parliamentary Secretary to the Local Government Board, received a deputation from the Sanitary Inspectors' Association, who represented to him the insecurity of the tenure of office by sanitary inspectors and the meagre rate of their remuneration, and suggested various measures by which their position might be improved.

The deputation was introduced by Sir Benjamin Ward Richardson, and amongst those present were Mr. Thomas, chairman of the council of the Sanitary Inspectors' Association and chief sanitary inspector for Bermondsey, Mr. Alexander, vice-chairman of the council, Mr. Wilkinson of Derby, Mr. Sumner of Wigan, Mr. Jacklin of Maidstone, and twenty metropolitan inspectors. Mr. Hayes Fisher, M.P. for Fulham, also accompanied the deputation.

Sir BENJAMIN RICHARDSON, in introducing the deputation, said:—"Sir, in addressing you to-day as President of the Association of Sanitary Inspectors, I desire to speak with you mainly on two points—firstly, the tenure of their office by sanitary inspectors, and secondly the amount of their remuneration. I should say that this matter has been brought to a crisis by the manner in which Mr. Watson, the sanitary inspector for the Burton-on-Trent district (who is here to-day), has been treated by his board. He was for thirty years inspector of the district, from which he has now been removed. He received in the first instance £215 a year, which was reduced to £175 upon the division of his district in 1888. Now there is another division in his district, with the result that new inspectors have been elected for each division and he is thrown out altogether. He has not been appointed to anything else, and although he knows the district so well, and has worked in it so long respected by everyone, he is, by this action of the county council, deprived altogether of his means of livelihood. This is not a solitary instance, although it is perhaps the most striking. All over the kingdom men are being thrown out in this way. We earnestly hope that some change will be made which will ensure to these gentlemen a respectable living and something in the way of a pension afterwards. I know that it may be said that at the present time the Local Government Board has no power whatever in these matters, and that you are obliged to do what has been done before; but we are somewhat doubtful whether this is the case. We of course accept at once that you have no direct power, but you have negatively and indirectly a great deal of power. But we want you to go further than that. We want you to bring about a change in the Act, so that security of tenure may be given to all sanitary inspectors. This is the only way in which injustice can be prevented. I also speak strongly on behalf of sanitation. Good sanitation cannot take place in England under the circumstances which now exist. These inspectors were originally appointed to assist the medical officer of health in his duties; but as time went on the work increased, and the sanitary inspector now has duties to perform which are not dependent on the medical officer at all. Therefore we think that the time has arrived when not only medical officers but also the sanitary inspectors everywhere should have a more secure tenure of office. We think also that in no case should the salary be less than £200 a year. An inspector who has gone through a proper education and passed an examination should receive a minimum of at least £200, rising to a maximum of £350. (I am surprised that inspectors should think that it ought to stop at £350.) They would then feel that they could perform their duties irrespectively of all personal interests and quite independently. We also think that there should be some retiring pension, which should be calculated on the same basis as other pensions are."

Mr. THOMAS pointed out the difficulties of the position of sanitary inspectors. "We need protection," he said, "in our work for various reasons. Local sanitary authorities are composed of interested persons—men who carry on offensive trades, lodging-house keepers, milkmen, butchers, grocers, &c. There is probably not one parish in England where an inspector does not have to interfere with the interests of some member of his authority in sanitary matters, nor one who can carry out his duties without fear or favour. It is

common for us to be threatened by tradesmen, against whom we are obliged to proceed in carrying out the Food and Drugs Act, that they will come on the board and see that we are disturbed from our office. We do not want to be protected when we are in the wrong, but we do want to be protected when we are in the right."

Mr. ALEXANDER, Mr. HAYES FISHER, M.P., and Mr. WILKINSON spoke to the same effect.

Sir WALTER FOSTER, in replying to the remarks that had been made, said:—"It gives me great pleasure to meet you here to-day as the representatives of so important a body of public officers as the sanitary inspectors of England and Wales. There are, I find, some 1600 of you in the country holding these offices at very varying salaries, under very varying conditions of tenure, and also under very varying conditions of efficiency—conditions of efficiency which are, however, I am glad to say, on the whole highly satisfactory and highly creditable to the gentlemen who do their work under so many difficulties and often with very little encouragement. I must say that one remark in the address of your President struck me very forcibly. He referred to the difficulty of carrying out efficiently sanitary work under present conditions—I think he said that it was almost impossible. I do not agree with him in that. I think that, looking at the existing conditions, one may well be surprised that these duties have been so ably carried out as they have been. You have certainly discharged your duties with a marvellous amount of efficiency as regards the saving of public life. This fact struck me particularly when some weeks ago I was looking over the result of this Board's work in reference to the Cholera survey which was undertaken by the Medical Department of this Board before and after the invasion of cholera in 1893. You will remember that in that year this country was placed in a situation of great peril. Although the ports of Western Europe were centres of infection there was during the whole time free intercourse between this country and those ports. Commerce went on as if there was no plague in the west of Europe. The danger was indeed very great, and the invasion threatened to be very fatal. To meet these difficulties we depended entirely on the sanitary service of the country. We had no quarantine and no interruption of traffic. You remember, most of you, that we have had invasions of cholera on two or three occasions previously and that it has been of a very fatal character. In 1849 we lost 53,293 lives, in 1854 20,097, and in 1864 14,378. When in the face of these figures one looks back upon the year 1893 one is struck by this fact—that although cholera did break through our outer line of defence, did get into our country and effect a lodgment in sixty-four places, yet in forty-two of those places the disease was stamped out with a single case and in only five instances did the disease extend beyond ten cases, our total loss being only 135 lives. When one considers that and compares it with previous results it seems to me one of the most marvellous triumphs of sanitation over the spread of cholera in the world's history; and after giving their full share of credit to the permanent officials of this Board, who, from Dr. Thorne downwards, worked most laboriously during the whole period, these results must to a very large extent be admitted to be due to efficient local sanitary work, inasmuch as on that depend the preservation of the purity of our water-supplies and the prevention of contamination air and soil. If this condition of things has so reduced cholera mortality you must have done your work throughout the various portions of the country with great efficiency, and I as a representative of this department would thank you for the efficient manner in which you have done your work during the last few years. The results to which I have alluded may be brought home to you by this fact: if we had had in England in the year 1893 a mortality from cholera in proportion to that of 1864—the least fatal of previous invasions—instead of 135 deaths we should have had 19,965, and thus 20,000 lives were practically saved in that single year by the efficiency of the sanitary service. It is impossible to estimate how much sorrow and want and pauperism were thus averted, and I hope every local authority will learn from this that the truest economy they can practise is the enlightened administration of the Public Health Acts and the placing of their sanitary officials in such a position that they can do their duties fearlessly. You will see that personally I am in sympathy with you and that I appreciate the great results which follow from the efficient discharge of your laborious and dangerous duties. I agree with Sir Benjamin Richardson that the life of a sanitary inspector is undoubtedly as perilous as that of the

soldier. While, however, from these remarks you may recognise that I have the strongest sympathy with you, I want you to bear in mind that we, the Local Government Board, can only go so far as the law will allow us. Your first demand is in the direction of having security of tenure. The law does not at present give you that position, and it would require the passing of an Act of Parliament to give you the security of tenure you desire. I do not see any prospect of time being at the disposal of the House of Commons for the passing of such an Act during the present session. If, however, an amendment of the Public Health Acts is brought forward at any time I shall do my best to support it and shall remember the arguments which have been so ably placed before me to-day. I have no doubt that in so doing I could count on the support of Mr. Hayes Fisher and other members on that side of the House. I wish also to say that, although up to the present time the Local Government Board have been in the habit of recognising appointments for one year only, we have done this on account of the hitherto uncertain areas of local government in this country; but now that the form of government has become settled and the country has been mapped out into more suitable governing districts we shall be in a position to take a different attitude towards this question. The Board are prepared to use their influence (within all proper limits) with the various local authorities to do away with these short-period appointments and to encourage local authorities everywhere to make these appointments for a term of years or, if possible, permanently, believing that, under such circumstances, the duties of sanitary inspectors would be discharged more fearlessly and with much more benefit to the public. The Board are prepared to go thus far without an Act of Parliament, but in course of time I hope an Act will be passed to bring about the changes desired. With reference to the salaries, I find that you are not as a body properly paid. I find that in many cases the salaries are exceedingly small, and I must say that when you suggested £200 as a minimum I could not help contrasting it with the actual state of affairs. I find there are some sanitary inspectors receiving only £5 a year, and some others, even where there is part repayment by the county council, receiving salaries of £10 a year. I fear that in many cases these salaries are not paid with a view to the discharge of onerous duties, but are given for services which are supposed by the local authorities to be nominal, but which you very well know are not nominal and ought not to be. You may be sure that we shall endeavour as far as possible to secure more adequate remuneration for these posts. We have discouraged and raised objections in many instances to these inadequate salaries. But you must remember that the Local Government Board cannot govern and control local matters to the extent which many of you seem to desire; we can never become a strong central authority such as you would like. In the evolution of government in the country more and more power must go to the local authorities; the whole bent and bias of modern development is in that direction, and it is to local bodies, therefore, that you must primarily look for redress. This Board will be a guiding and sanctioning body; it cannot be a constantly interfering one; but I can assure you that you will always have from the Local Government Board such sympathy and help as they can give. The salaries must, of course, to a large extent depend upon the local authorities, though in all cases the tendency of the Board will be to encourage proper and liberal, rather than inadequate, payments for such valuable services as you render to the community. As regards pensions, you must work that question out for yourselves on the same basis as the Poor-law officers throughout the country are now doing. There are Bills now before the House brought in by private members dealing with the question. I direct your attention to them with a view to your getting yourselves included in the scheme. There is a strong feeling against pensions, public opinion being more in favour of salaries being paid at such a rate as would lead to the abolition of pensions; but if the system is to be continued I see no reason why it should not be extended to sanitary officers as well as to other officials. Lastly, with reference to the very hard case of Mr. Watson (for it must be admitted that it is a very hard case), you must, I think, recognise that it is one of those cases in which the Board has no real authority. The statute of 1894 enables local authorities to make these changes in the areas under their control, and gentlemen who are unfortunately in the position of having their appointments renewed from year to year may be dismissed by these authorities. But I should hope that

local authorities will not forget the faithful services rendered by these gentlemen, and that they will feel that such officers have a moral claim upon them, and that they will not on the sole ground of economy put these claims on one side and use their powers harshly."

Sir BENJAMIN RICHARDSON then thanked Sir W. Foster, and the deputation withdrew.

ALDERSHOT: THE SANITARY AND SOCIAL CONDITIONS.

THERE have been so many rumours and reports concerning the sanitary condition of Aldershot that it will tend to relieve unnecessary anxiety to show what is the actual state of affairs. Briefly, it must be explained that there are two systems of drainage—that of the town and that of the camp. Of course, it would be much better to amalgamate the two; that is a point beyond dispute. The difficulty has been to effect an arrangement between the civil and military authorities and to settle how the expenses should be shared between these two independent and widely different bodies. Aldershot as a town has very rapidly developed of late years. From a hamlet with a few hundred inhabitants it has become a little town with a population of about 14,000. The town, under these circumstances, has the advantage of being built on virgin soil, a soil which has never been contaminated by old cesspools and where sewers were laid down as fast as houses were built. But difficulties have arisen with regard to the disposal of the sewage thus collected. Some twenty years ago the town of Aldershot contracted with a firm for the treatment and clarification of this sewage before its discharge into the river Blackwater; but the method of treatment was not satisfactory. Complaints were made that the river was befouled, and a neighbouring authority lower down the stream entered an action against the Aldershot authorities. They gained their point. Judgment against Aldershot was obtained, and injunctions to restrain from polluting were given. Under these distressful circumstances, the town took the sewage works out of the hands of the contractor, who fortunately made no resistance, but seemed, on the contrary, glad to escape from all the difficulties that had arisen. The town authorities now tried various processes of purification, and discovered that, probably in consequence of the large number of horses at Aldershot, their sewage was stronger than that of most towns, and methods of purification which gave satisfaction elsewhere did not act with sufficient energy at Aldershot. Also there was the fact that not only was the sewage stronger, but that the river is small. Thus an affluent was produced by a lime process which if thrown into a large river would cause no trouble. It was clear, free from colour, and looked pure, but still contained organic elements in solution. A large volume of water and a rapid current would have oxidised this small quantity of remaining impurity, but in the comparatively stagnant waters of the Blackwater a secondary decomposition set in. Lower down, in bends of the river, black deposits were formed which, under the heat of the summer sun, soon became obnoxious. The local authorities, after taking advice, abandoned lime as a precipitant, and have since utilised Gibb's alumina. Cakes of this precipitant are placed at the bottom of a trough and the sewage is pumped up through them. After the precipitation is over the water is thrown on to land. So that the filtration may be more perfect some thirty more acres of land have been purchased. The land slopes; the clarified sewage is discharged on the soil at the highest point, and is collected again at the lowest point in a trench dug some 5 ft. deep near the river bank. On the grounds some root crops and rye grass are grown. In rainy weather as many as a million gallons of sewage have been treated and pumped upon this ground in the twenty-four hours. The average outfall of sewage is from 600,000 to 650,000 gallons per day, and this for a civil population of some 15,000 persons. In spite of these improvements in the treatment of their sewage, some twelve months ago the Aldershot authorities were again convicted by the County Court for polluting the river. Feeling that, under the altered circumstances, this was not a fair judgment, the Aldershot authorities carried the case before the Court of Appeal in London and here they were successful. The Court of Appeal decided that the Aldershot authorities were using the best available means and gave

judgment in their favour with costs. Indeed, according to analyses, the result seems very good. For instance, the analysis made by Professor John Attfield on Jan. 25th last shows that per gallon there were 41.0 grains total solids, 1.68 grains of free ammonia, 0.09 grain albuminoid ammonia, and 5.7 grains of chlorine in chlorides. Professor Attfield adds the following comment: "This sample is in a most excellent condition. Such an affluent may safely be admitted into any stream."

Such, briefly, is the history of the town drainage, so far, at least, as the treatment of the sewage is concerned. When, in the time of the Crimean War, the camp was first built there was no town of Aldershot, no sewage, and no sewage treatment. The military authorities, therefore, had to take this matter in their own hands, and they selected a spot which was to be made into a sewage farm. But the knowledge of such questions in those days was not very great; in any case a most unsuitable site was selected. Instead of a sandy, porous soil, which can act as a natural filter, it is a low peaty deposit, which cannot absorb the large volume of camp sewage it receives. As a consequence a good deal of the sewage is not treated at all, but allowed to escape in any condition. This camp sewage farm has been the great cause of complaint for many years, and it certainly ought to be abolished. For this purpose, and at the instigation of the camp medical officer, the town approached the War Department and suggested that experts appointed by the War Office should meet experts appointed by the town and see if some means could not be devised for united action between the civil and military authorities to drain both camp and town together. This meeting was ultimately held, but the course of action then recommended was not adopted. Nevertheless, the need of some agreement was very pressing and became particularly acute when the old wooden huts were pulled down and replaced by handsome red brick barracks. Negotiations were resumed, but the great difficulty rested in the fact that the military authorities were not ratepayers. They certainly subscribed of their own free will a certain small annual sum towards the town expenses, but the camp is not rated, and if the town authorities undertook to drain the camp they would have to deal with double the amount of sewage. The town authorities stood fast to the principle that they were quite willing to drain the camp if the camp would pay rates; otherwise they must leave the camp to its own devices. This led to interminable negotiations with the Treasury, particularly as it is absolutely impossible to estimate the rateable value of a camp. Rateable value is generally estimated at what rent would be paid to occupy the property in question if it was vacant. But if the 14,000 or more soldiers who live in the camp buildings were all taken away not only would it be impossible to find tenants for their barracks, but the town of Aldershot itself would very soon dwindle and lose the greater part of its inhabitants. However, in spite of all these obstacles a sum has at last been fixed acceptable to both parties, and this annual sum or rate being paid by the War Department to the Aldershot Local Board, the latter authority will take over the drainage of the camp. We may hope, therefore, that the abominations of the camp sewage farm will soon disappear, and there will be no further cause for anxiety on this head. The sewage of the camp will be as carefully clarified as is that of the town. We propose to deal with the subject of Venereal Disease at Aldershot in a future number.

(To be continued.)

PROVISION FOR YOUNG IMBECILES.

At the quarterly meeting of the Lancashire Asylums Board, held in the county hall at Preston on Feb. 28th, it was announced that the Local Government Board had sanctioned the borrowing of £26,582 for additions and completions at Lancaster, Prestwich, and Whittingham Asylums. It is agreeable to note that a vote of congratulation was passed to Dr. Wiglesworth of Rainhill Asylum upon his restoration to health after a serious attack by a lunatic named Horan, who was afterwards removed to Broadmoor as a criminal lunatic. The chairman, the Rev. T. C. Royds, stated that the West Derby board of guardians had passed a resolution in favour of special provision at the new asylum at Winwick or elsewhere for young persons and children of

weak intellect. Mr. H. P. Cleaver, on behalf of a combined deputation of guardians, explained that they had come on behalf of an unfortunate class of the population unable to plead their own cause, and for whom no adequate provision was made in the north of England. The Royal Albert Asylum at Lancaster was practically useless so far as the pauper class was concerned. Neglect of these cases was costly and it was a disgrace to the community that no provision had been made for epileptics. Mr. Cleaver further stated that there were 214 cases in the workhouses of young people requiring special treatment, and it would be impossible to say how many more were kept at their own homes—at least treble the 214, he should estimate. Mr. A. Grey of Lancaster said his recollection was that the seven northern counties contained about 7000 cases, of which over 2000 were in Lancashire. The Royal Albert Asylum provided for about 600 out of the whole seven counties. There were 136 cases in the Lancashire workhouses, and nearly 200 in county lunatic asylums. The chairman said the deputation had made out a very good case for the careful consideration of the Board. Experience showed that only a small percentage of imbeciles and idiots were curable, and he did not think the ratepayers were prepared to spend as a start at least £250,000 for an institution for weak-minded children, besides the cost of maintenance of such an institution. His suggestion as a temporary measure, to supplement the private benevolence, would be that the juvenile idiots in workhouses should be medically examined, and where there was thought to be a prospect of improvement that they should be sent for a probationary period, at the cost of the ratepayers, to the Royal Albert Asylum. Children not favourably reported upon, or returned unimproved, should be kept in isolated wards of the workhouses, with separate airing grounds, so that the other inmates might not be afflicted by their presence and the imbeciles might not learn rough habits. Dr. J. M. Rhodes (Chorlton) said census returns were of no value on this subject, as by personal inquiry in pronounced cases known to himself he had found that not 20 per cent. were returned as weak-minded. The Royal Albert Asylum rightly refused cases of epilepsy, because non-epileptics deteriorated in the presence of epileptics. He would remind the Board that many of these children for whom the deputation had pleaded were girls unfit to resist the temptation of any scoundrel, with results costly to the ratepayers and sadly deteriorating the population.

THE OBSTETRICAL SOCIETY OF LONDON AND ITS "DIPLOMA."

THE following is a specimen of the document in full as given by the Obstetrical Society to midwives who pass their examination.

[COPY.]

OBSTETRICAL SOCIETY OF LONDON.

We hereby certify that has passed to our satisfaction the examination instituted by the Obstetrical Society of London, and that she is in our opinion a skilled midwife competent to attend natural labour.

G. ERNEST HERMAN, M.B., President.	
F. H. CHAMPNEYS, M.D., Chairman.	
JOHN PHILIPS, M.D.,	} Examiners.
AMAND ROUTH, M.D.,	
M. HANDFIELD-JONES, M.D.,	} Honorary Secretaries.
WILLIAM DUNCAN, M.D.,	
WM. DAKIN, M.D.,	

I undertake to abide by all the rules and regulations of the Obstetrical Society with regard to all the duties and conduct of midwives, and to submit to the jurisdiction of its council in the decision of all matters relating to my conduct as a midwife. I further agree that in case I shall be hereafter convicted of any criminal offence or be guilty of any act or conduct which in the opinion of the council renders me unfit or unworthy to hold its diploma, the same may be forfeited by a resolution of the council, in which case I will, on receiving notice in writing of such resolution, to be served either personally or by having the same at my then present or last-named place of abode in the United Kingdom, forthwith give up such diploma to the President or to one of the secretaries for the time being of the society, and I agree that my name may be removed from the Register of Midwives kept by the society, and I promise henceforth to desist from the use of any designation or title implying possession of such diploma. (Seal)

At its recent meeting the Executive Committee of the General Medical Council, replying to a letter from the hon. secretary of the Obstetrical Society asking the General Medical Council to point out in what respect the certificate

of the society of examination in midwifery is a colourable imitation of a legal diploma, resolved: "That the Executive Committee are of opinion that the words in the diploma, 'a skilled midwife competent to attend natural labour,' are open to legal objection, seeing that under the Medical Act midwifery is one of the three branches in which a regular practitioner must pass an examination in order to obtain a registrable qualification. The above-cited words suggest that the holder has a registrable qualification. This both contravenes the spirit of the Medical Act of 1886 and is calculated to deceive the public. Again, the formal character of the document, which is described on its face as a diploma, is fitted to deceive the more ignorant part of the public, that part which most needs protection."

THE HALF-YEARLY REPORT OF THE MEDICAL OFFICER OF HEALTH FOR THE PORT OF LONDON.

BLUE-BOOKS as a rule are not particularly interesting specimens of literature, but the one now under notice is an exception to the rule, especially when we read it in the light of the recent debate on the Navy, during which an honourable member mentioned that the British mercantile marine formed one half of that of the whole world. In this report we find that in the latter half of 1894 13,471 vessels were inspected within the Port of London, of which 81.9 per cent. were British, Scandinavian coming next with 8 per cent. In 266 ships 343 structural alterations were ordered and carried out; 114 were for increased ventilation of crews' quarters and 47 were alterations with regard to water-supply, mainly the substitution of galvanised iron tanks for rotten casks. Of the total number of vessels, 6880 were foreign traders and 6591 coasters. The report recalls the recommendations of the Royal Commission on Labour, whereby the proper amount of cubic space allotted per man was laid down as 120 feet, and compares it with the Merchant Shipping Act of 1894, which re-enacted the old amount of space—viz., 72 cubic feet. This Dr. Collingridge considers quite inadequate. On the arrival of a vessel she is inspected medically in conjunction with Her Majesty's Customs. The total number of vessels medically inspected for 1894 was 1868, and the number of individuals averaged about 100 per day, while as a result of this inspection twenty-seven cases of infectious disease were discovered. All masters are bound to report any case of illness which has occurred either during the voyage or during the stay in a foreign port. During the year 3425 Jewish alien emigrants were inspected at Gravesend, and it is satisfactory to note that they arrive "in a much cleaner condition than formerly," owing to the knowledge that they will be inspected at Gravesend. Another satisfactory result of medical inspection is that owing to the issuing of orders at Gravesend for water-tanks to be emptied if the ship has come from an infected port the practice has been adopted of filling up tanks on this side for the outward and homeward voyage. Since September, 1894, all vessels entering the Medway have been inspected by a medical officer stationed at Garrison Point.

Some few cases of cholera and choleraic diarrhoea were dealt with at Gravesend, and diarrhoea has been made a compulsorily notifiable disease. The other infectious diseases dealt with were chiefly enteric fever and diphtheria. A serious nuisance has been caused by barges carrying dung from cattle ships. It is the habit of these barges to load partly in one dock and then to proceed to another to complete their freight instead of going away at once. Steps have been taken to prevent this.

The Kensington vestry have again commenced to deposit refuse dust at Purfleet, causing a nuisance, but it is expected that an amicable arrangement between the various authorities concerned will soon be arrived at.

The Port hospital is working well, and has been extremely useful. The seizures of unsound food have been about the average. During the year 909 canal boats were inspected, but only three prosecutions were found necessary, and "as a general rule the cabins are cleanly and wholesome."

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

*Diphtheria at Broadstairs, by Dr. BRUCE LOW.*¹—The outbreak in question had its principal interest during the visiting season of 1894, but the report on it was only made at the close of the year. Including each of the three subdivisions of the urban district, 31 attacks of diphtheria occurred in Broadstairs between Jan. 1st and Aug. 8th of last year, and in 11 instances the attacks terminated fatally. There were two localised outbreaks—one in the suburban portions of the district and one in the Broadstairs division, but this latter was confined to one establishment. The first outbreak was probably traced to imported infection, for it occurred in the house of a woman who acted as laundress for a convalescent home receiving London children. Eighteen attacks occurred as the result, and 15 of the patients were removed to the isolation hospital, a step which, in Dr. Low's opinion, largely contributed to stay the further spread of the infection. In the case of the second outbreak diphtheria was twice imported into a children's home. Once it was detected, precautions were taken and it was stopped. On the next occasion there was some diffusion of the infection in the dormitory where the patient originating the mischief had slept. But, on the whole, the interest in this inquiry, so far as the general public are concerned, lies in the fact that Dr. Low is able to assert with confidence that the disease was in no way due to local insanitary conditions. He also speaks highly of the sewerage of the place and of the prompt manner in which the existing means of isolation were utilised. The truth is that Broadstairs has a large colony of convalescent children and of poor children who are sent there for their health, and, as a consequence, it runs some unusual risk of imported infection; but the risk is practically limited to the institutions in question, it hardly applies at all to the town generally, and even in the "homes" prompt medical supervision may be trusted to identify any infectious disease that appears and to secure the immediate removal of the sick to the hospital which the town has been wise enough to provide for itself.

*On the General Sanitary Condition of Festiniog, by Mr. EVAN EVANS.*²—This report, by one of the temporary medical inspectors of the Local Government Board, gives a very complete account of the general sanitary condition of this Welsh urban district, which has suffered a good deal by the depression in the slate trade, although at the time of the inspection work seemed plentiful and wages good. The Blaenau villages, comprised within its district, are perhaps those which most call for remedial sanitary measures, these measures being very largely wanted by reason of the evils resulting from the non-completion of a system of sewerage and drainage. The general water-supply is from the Morwyion Lake, but other sources are resorted to because the water supplied by them appears to be clearer to the eye. In this way springs, spouts, and mountain rills afford a supply; but since these sources are often near to privies and privy pits the risks of their contamination is by no means inconsiderable. Streams, too, are seriously affected in several ways. Thus the want of sewerage leads, during periods of drought, to extensive and offensive fouling of small watercourses by liquid refuse; and the form of privy known as a "water privy," so styled because it is built over a stream, constitutes another obvious and grave nuisance; indeed, such a system ought to be regarded as a thing to be prohibited by any sanitary authority. In this district excreta accumulate on the banks of the stream, and when rain falls the decomposing material is swept into the immediate vicinity of dwellings. Many of the principal defects of the populous areas in this district would be remedied if the authority would complete their sewerage scheme, and this has more than once been pressed upon them by their medical officer of health. The bringing in of good water as a public supply has already caused a distinct lowering in the typhoid fever death-rate,

¹ Eyre and Spottiswoode, East Harding-street, E.C.; John Menzies and Co., Edinburgh and Glasgow; Hodges, Figgis, and Co., Grafton-street, Dublin. Price 3d.

² Ibid., price 9d.

and has thus shown the value to health and life of proper sanitary expenditure; but the lesson has as yet been lost as regards other diseases, such as scarlet fever &c., which need to be coped with by means of isolation. No isolation hospital has been provided, and partly by reason of the absence of any such provision diphtheria was recently very prevalent in a part of the district. Mr. Evans's report is an excellent example of a very complete examination into the sanitary conditions and administration of a district such as the one here involved.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6914 births and 6534 deaths were registered during the week ending March 16th. The annual rate of mortality in these towns, which had increased in the seven preceding weeks from 18.7 to 35.0 per 1000, declined again last week to 32.2. In London the rate was equal to 33.4 per 1000, while it averaged 31.3 in the thirty-two provincial towns. The lowest rates in these towns were 15.6 in Norwich, 20.7 in Leicester, 21.3 in Derby, 22.1 in Blackburn, and 22.9 in Hull; the highest rates were 36.4 in Bradford, 37.1 in Liverpool, 40.3 in Preston, 44.0 in Oldham, and 48.0 in Brighton. The 6534 deaths included 302 which were referred to the principal zymotic diseases, against 330 and 339 in the two preceding weeks; of these, 113 resulted from whooping-cough, 52 from diphtheria, 51 from measles, 31 from diarrhoea, 27 from "fever" (principally enteric), 22 from scarlet fever, and 1 from small-pox. No death from any of these diseases was recorded last week in Leicester, Huddersfield, or Halifax; in the other towns they caused the lowest death-rates in Cardiff and Blackburn; and the highest rates in Manchester, Bolton, Croydon, Newcastle-upon-Tyne, and Burnley. The greatest mortality from measles occurred in Plymouth, Bolton, Manchester, and Sheffield; and from whooping-cough in Croydon, Swansea, Liverpool, Gateshead, and Burnley. The mortality from scarlet fever and from "fever" showed no marked excess in any of the thirty-three large towns. The 52 deaths from diphtheria included 27 in London, 4 in West Ham, 4 in Birmingham, and 3 in Sheffield. One fatal case of small-pox was registered in London, but not one in any of the thirty-two provincial towns. There were 57 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, March 16th, against 75, 68, and 56 at the end of the three preceding weeks; 12 new cases were admitted during the week, against 19, 8, and 8 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1615, against 1658, 1621, and 1619 on the three preceding Saturdays; 133 new cases were admitted during the week, against 152, 143, and 141 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had increased in the seven preceding weeks from 324 to 1366, declined to 1031 last week, but were as many as 507 above the corrected average. The causes of 98, or 1.5 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Cardiff, Oldham, Bradford, Sunderland, and in eight other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Blackburn, Preston, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 42.8 and 40.9 per 1000 in the two preceding weeks, further declined to 35.1 during the week ending March 16th, but exceeded by 2.9 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 18.7 in Aberdeen and 23.2 in Dundee, to 41.4 in Paisley and 45.8 in Edinburgh. The 1014 deaths in these towns included 48 which were referred to measles, 22 to whooping-cough, 22 to diarrhoea, 10 to scarlet fever, 4 to diphtheria, 3 to "fever," and 1 to small-pox. In all, 110 deaths resulted from these principal zymotic diseases, against 115 and 144 in the two preceding weeks. These 110 deaths were equal to an annual rate of 3.8 per 1000, which was 2.3 above the mean rate during the

same week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 51 and 72 in the two preceding weeks, declined to 48 last week, of which 19 occurred in Edinburgh, 15 in Glasgow, 5 in Leith, and 4 each in Aberdeen and Paisley. The deaths referred to whooping-cough, which had been 30 and 39 in the two preceding weeks, declined to 22 last week, and included 14 in Glasgow and 4 in Dundee. The 10 fatal cases of scarlet fever exceeded by 4 the number in the preceding week, and included 7 in Glasgow and 2 in Edinburgh. The deaths from diphtheria, which had been 7, 5, and 8 in the three preceding weeks, declined again to 4 last week, of which 2 occurred in Glasgow and 2 in Leith. The 3 deaths referred to different forms of "fever" included 2 in Glasgow, where the fatal case of small-pox was also recorded. The deaths referred to diseases of the respiratory organs in these towns, which had been 544 and 463 in the two preceding weeks, further declined to 385 last week, but exceeded by as many as 279 the number in the corresponding week of last year. The causes of 67, or nearly 7 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 32.7 and 48.6 per 1000 in the two preceding weeks, declined again to 42.4 during the week ending March 16th. During the past eleven weeks of the current quarter the death-rate in the city has averaged 35.3 per 1000, against 26.4 in London and 30.2 in Edinburgh. The 284 deaths registered in Dublin during the week under notice showed a decline of 43, from the number in the previous week, and included 9 which were referred to the principal zymotic diseases, against 6 and 14 in the two preceding weeks; of these, 4 resulted from small-pox, 3 from whooping-cough, 1 from diphtheria, 1 from diarrhoea, and not one either from measles, scarlet fever, or "fever." These 9 deaths were equal to an annual rate of 1.3 per 1000, the zymotic death-rate during the same period being 1.4 in London and 5.5 in Edinburgh. The fatal cases of small-pox, which had been 6, 4, and 5 in the three preceding weeks, declined again to 4 last week. The 3 deaths referred to whooping-cough corresponded with the number recorded in the preceding week. The 284 deaths registered in Dublin last week included 36 of infants under one year of age, and 82 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a marked decline from the very high numbers recorded in the preceding week. Two deaths from violence, but no inquest cases, were registered during the week; and 83, or nearly a third, of the deaths occurred in public institutions. The causes of 15, or more than 5 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

SURGEON-MAJOR RECKITT has embarked for Jamaica on exchange. Surgeon-Major Le Motté and Surgeon-Captain Hassam have been posted to Aldershot. Surgeon-Captain Duncan has arrived in Malta. Brigade-Surgeon-Lieutenant-Colonels Price and Riordan have arrived home after a tour of service in India and Cyprus respectively. Surgeon-Colonel Maunsell has embarked for Bombay. The following officers have arrived from India in the *Dilwara*:—Surgeon-Majors Bartlett and Semple; Surgeon-Captains Pocock and Reilly. Surgeon-Captain Thacker has been transferred from Aldershot to Dublin.

ARMY MEDICAL STAFF.

Brigade-Surgeon-Lieutenant-Colonel William Sparks Martin Price to be Surgeon-Colonel, vice W. C. Robison, retired. Surgeon-Lieutenant-Colonel James Maybury Beamish, M.D., to be Brigade-Surgeon-Lieutenant-Colonel, vice W. S. M. Price.

INDIA AND THE INDIAN MEDICAL SERVICES.

The Queen has approved of the retirement of the under-mentioned officers: *Bengal Medical Establishment*: Brigade-Surgeon-Lieutenant-Colonel William Roe Hooper, Surgeon-Lieutenant-Colonel Alexander Bannerman Strahan. *Bombay Medical Establishment*: Surgeon-Lieutenant-Colonel John Alexander Howell. Surgeon-Lieutenant-Colonel M. M. Galloway temporarily assumes Medical Charge of the Mhow district, vice Surgeon-Colonel Gore. Surgeon-Captain A.

Street, having taken over the medical charge of the 1st Bombay Grenadiers from Surgeon-Lieutenant H. M. Moore, the latter is transferred to the Quetta district on general duty. Surgeon-Lieutenants J. G. McNaught and H. A. Bray, A.M.S., shortly expected to arrive in India, are posted to the Bombay Command. Surgeon-Major E. F. H. Dobson, M.B., Civil Surgeon, is posted to the Gwalpara district. Surgeon C. O'Connor Hodgkins, A.M.S., is, on arrival in India, posted to general duty, Nagpore district. The following postings are made in the Madras Command: Surgeon-Captain B. F. Zimmermann and Surgeon-Captain M. Kelly, A.M.S., to the Southern district for duty; Surgeon-Captain W. Gibbard, A.M.S., to do duty in the Chin Hills Command; and Surgeon-Captain R. L. R. McLeod, A.M.S., to do duty in the Secunderabad district. Surgeon-Major J. C. H. Peacocke is to be Civil Surgeon, Karwar, but to continue to act as Civil Surgeon, Belgaum; and Surgeon-Captain H. C. L. Arnim to be Deputy Sanitary Commissioner, Sind Registration district. Brigade-Surgeon-Lieutenant-Colonel S. M. Salaman, Superintendent of the Yeroda Central Prison, in the district of Poona, is appointed to be a Magistrate of the Third Class in that district. Surgeon-Lieutenant A. E. Berry, I.M.S., is appointed to be, in addition to his medical duties, the Civil Medical Officer, Falam Chin Hills.

NAVAL MEDICAL SERVICES.

Staff-Surgeon Archibald McKinlay has been promoted to the rank of Fleet-Surgeon.

The following appointments are notified:—Staff-Surgeon R. E. Biddulph to the *Dreadnought*. Surgeons: R. S. Bernard to the *Bonaventure*; J. C. Wood to the *Minotaur*; S. H. Birt to the *Lion*; J. Grant, M.B., to the *Mosquito*; W. Bett to the *Inferrible* (lent); J. Down to the *Duke of Wellington*; G. R. McMahon to the *Dreadnought*. Surgeons and Agents: E. B. Cutting at Maudesley, C. F. Rudd at Palling, Bacton, &c.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain James William Thornton Gilbert, 1st London Volunteer Artillery, to be Surgeon-Captain. Surgeon-Captain Robert Launcelot Sparrow, 6th Volunteer Battalion the Manchester Regiment, to be Surgeon-Major.

VOLUNTEER CORPS.

Rifle: 1st (City of Dundee) Volunteer Battalion the Black Watch (Royal Highlanders): James Samuel Yeaman Rogers, M.B., to be Surgeon-Lieutenant.

THE LATE OUTBREAK OF CHOLERA IN THE JAMSETJEE JEJEEBHAY HOSPITAL, BOMBAY.

It will be remembered that the Government of Bombay instituted an inquiry into the cause of the late outbreak of cholera in this institution, and that the Surgeon-General sent in a very exhaustive report on the subject, in which, however, one point was raised as to its possible cause, which was not thoroughly threshed out at that time. The "Medical Union" of Bombay had, in the meantime, asked the Government for an independent inquiry, and the Government had also requested to be supplied with a further report as to the provision, preparation, distribution, and cooking of the food supplied to the patients in the hospital—the point which the Surgeon-General had raised as affording a possible clue to the cause of the outbreak in question. Our readers will probably be interested in learning the results. The Government of Bombay have replied to the "Medical Union" that they consider further inquiry unnecessary, and, as regards the results of the further investigation into the food supply, we understand that the evidence fails to furnish any conclusive evidence that it was connected with the cause of the outbreak.

PARKES MEMORIAL PRIZE.

This triennial prize of seventy-five guineas and a gold medal for the best essay on "Malarial Fevers: their Causation and Prevention," illustrated as far as practicable by facts personally observed by the writer, has been awarded to Surgeon-Major R. Ross, of the Indian Medical Service. The assessors by whom the prize was adjudged were: Dr. Veale, Dr. Patrick Manson, and Professor A. E. Wright. The essays were eleven in number, and the assessors were unanimous in allotting the first place to that bearing the motto, "Da nobis lucem, Domine," which, on opening the sealed envelope, was found to be the work of Surgeon-Major Ross. The other essays will be returned on application to the Secretary, Parkes Memorial Fund, Netley.

Correspondence.

"Audi alteram partem."

THE MECHANISM OF ACCOMMODATION.

To the Editors of THE LANCET.

SIRS,—Some years ago, by the kindness of my friend, the late Dr. Garrod, while he was prosecutor to the Zoological Society, I was enabled to compare a great variety of eyes in birds and mammalia. The chief objects of inquiry were the structure of the ciliary muscle, and of the iris, and the shape and size of the lens. I must say that there seemed to be strong evidence in favour of the view that the lens is not altered in shape but in position, and looking back to the idea put forward originally by the great Dr. Young (that the lens alters its shape), it seems that this view was wisely abandoned by him after later consideration. When we recognise the visual powers of the birds and fish, and see how inferior our powers are in comparison with them, I think it well to look into the theory of alteration of shape with greater care than it has yet received.

I am, Sirs, yours faithfully,

ROBERT LEE.

March 20th, 1895.

* * We have no doubt the conclusions drawn by our correspondent from his observations will be of value. That there is some uncertainty upon the points to which he refers is clear from the fact that a paper was read by Dr. Tscherning before the Ophthalmological Congress which met at Edinburgh last year on the mechanism of accommodation, in which a new and ingenious view of the nature of that process was advanced and supported by good reasoning; but Dr. Robert Lee should read through the chapter on this subject in the second part of the *Physiologischen Optik*, of Professor H. V. Helmholtz, and that by Professor Landolt in his *Treatise on the Refraction and Accommodation of the Eye*.—ED. L.

"THE TREATMENT OF INFLUENZA."

To the Editors of THE LANCET.

SIRS,—Most practitioners will, I imagine, concur with the warning issued by Dr. Burney Yeo and Dr. Moffat against over-treatment in influenza. I have no difficulty in believing that adherence to the principles upon which Dr. Moffat bases his treatment will lead, in the majority of cases, to most satisfactory results; but when he enjoins on his patient the necessity of bearing philosophically the pains characteristic of the initiatory stage of the disease, and offers him only the poor consolation of an assurance that "they will disappear with the fever—i.e., in from one to three days"—I ask permission to join issue. In the numerous cases I have had to treat here in Paris since the first epidemic I have almost invariably been enabled to bring down the temperature and rid the sufferer of his pains in a few hours by the exhibition of four six-grain hourly doses (in cachets) of phenacetin. Should, as is rarely the case, pain and fever continue I prescribe two more cachets at intervals of four hours. At the same time I give every three hours an effervescent draught containing ten grains of potassium nitrate. Complications such as bronchitis must, of course, be treated on general principles, but I should certainly not feel justified in allowing my patient to pass the night coughing when an expectorant mixture with a small proportion of morphia would procure him relief. I have never noticed any ill-effects from this plan of administering phenacetin. Thanks to it, I almost invariably see my patient at my second visit smiling and absolved from the necessity of philosophically bearing what I consider is superfluous suffering.

I am, Sirs, yours faithfully,

Paris, March 19th, 1895.

J. H. BARNARD, M.D.

* * We print Dr. Barnard's letter with pleasure. We have received many others recommending highly the use of certain special drugs, old and new. Their publication can hardly be profitable, for it is clear that the limits of a letter are too restricted to allow of the exposition of evidence in favour of any one remedy for any

disease which shall suffice to carry conviction. Moreover, our space is limited.—ED. L.

"THE EAST-END MOTHERS' HOME."

To the Editors of THE LANCET.

SIRS,—You ask questions as to the East-end Mothers' Home which I ask leave to answer: 1. "At what period are patients discharged after confinement?" Fourteen days.—2. "Were any patients discharged who could not be fairly classed as quite well?" No.—3. "Were any patients who were seriously ill sent to their homes?" None.—4. "Or to some general hospital?" One suffering from erysipelas was removed to the London Hospital.—5. "Did any such cases die or only recover after a longer or shorter illness of more or less gravity?" In case above-mentioned, recovered.

I am, Sirs, yours faithfully,

London, E., March 18th, 1895.

M. C. CORNER.

ON CERTAIN PSYCHOLOGICAL PHENOMENA ACCOMPANYING THE ADMINISTRATION OF ANÆSTHETICS.

To the Editors of THE LANCET.

SIRS,—In the year 1800 Humphry Davy, then twenty years of age, experimented with nitrous oxide and suggested its use in surgical operations as a means of preventing pain, and in his biography we read that the impressions he received while under the influence of the gas induced him to exclaim to Dr. Kinglake, "Nothing exists but thought. The universe is composed of impressions, ideas, pleasures and pains." In the year 1874, while inhaling chloroform as a relief to the agony of passing a small renal calculus, I suddenly experienced the extraordinary impression that my spiritual being stood visibly outside my body, regarding that deserted body lying on the bed. Shortly afterwards I called on three different professional chloroformists and asked them if any of their subjects had ever experienced sensations like my own? In reply one gentleman said, "I have often heard patients express similar ideas." Another said, "I myself have experienced on three occasions, when under chloroform, exactly similar sensations." And the third gentleman said, "My patients have often said that they experienced no pain, but felt as if they saw with their inner eye all I was doing during the operations." I was told of a patient who said after anaesthesia, "I thought I was got at the bottom of the secrets of nature." And a dentist told me that many of his patients had experienced similar sensations to those I described.

Now, it is well known that those who have been rescued from drowning have often described their sensations while drowning as being pleasurable and their visions as transcendental. Similarly in the case of anaesthetics. The startling and significant fact is this: that while the body is as if dead under anaesthetics the imagination becomes active and at times exalted. Or, as another friend said to me, "When under chloroform the Platonic ideas came to me that Matter was only phenomenal, while the only reality was that which underlay Matter—viz., its spiritual substance." The object of this letter is to bring before the medical profession these psychological experiences when under anaesthetics; and as in Great Britain there are probably not fewer than 1000 individuals, including midwifery cases, daily placed under anaesthetics there should be an almost unlimited store of evidence to draw from, and thus most important facts may be arrived at as to the construction of an experimental psychology.

I am, Sirs, your obedient servant,

Wimbledon, Feb. 28th, 1895.

GEORGE WYLD, M.D. Edin.

"PLEURITIC EFFUSION WITH NEGATIVE PRESSURE IN THE PLEURA."

To the Editors of THE LANCET.

SIRS,—In the case under the care of Dr. Samuel West, published in THE LANCET of March 16th, there are several points of interest, but I wish to refer only to the one described under the above heading. Fluid was undoubtedly present in the chest, and paracentesis was performed twice with an ordinary trocar and long tube. On the first occasion no fluid

passed out, the "manometer pressure indicated four inches negative pressure of water with half an inch respiratory oscillation," and air passed into the pleural cavity from the outside. On the second occasion, three days later, "the manometer registered a positive pressure of four inches and a half of water, with a respiratory oscillation of an inch and a half," and ninety-seven ounces of fluid along with much air were removed. Dr. West regards the existence of a negative pressure of four inches of water with an increasing effusion as "almost inexplicable"; and according to the teaching of most of the text-books I think it may be regarded as not almost but altogether inexplicable. That teaching is to the effect that when any fluid is effused into the pleural cavity it at once exerts pressure on the lung, the heart, and other surrounding tissues, and consequently one is led to expect that when an opening is made into the chest the fluid will rush out. That this teaching is not in accordance with clinical facts has been known since the time of Trouseau, but, so far as I am aware, the problems remained unsolved until Dr. Douglas Powell¹ ascertained and explained the effects of lung elasticity. In health there is a (potential) negative pressure in the pleural cavity, and on the occurrence of effusion this is maintained until the elasticity of the lung is exhausted by its gradual retraction, when the pressure of the fluid becomes positive. Two distinct stages are associated with pleural effusion, the first when the pressure of the fluid is negative and it is held in suspense by the elasticity of the lungs, and the second when the pressure of the fluid is positive, the lung elasticity having been exhausted. In the first stage the introduction of a trocar will not lead to the evacuation of the fluid, but to the entrance of air from the outside, if an opportunity is presented; while in the second stage fluid will flow freely as long as a positive pressure exists. These facts I have frequently verified at the bedside, and Dr. West's case supplies confirmatory evidence. In testing them one further point must be noted—namely, that the patient must be breathing quietly and regularly, for if he cough or hold his breath fluid will be driven through the trocar, whatever the intra-pleural pressure may be, owing to the forcible elevation of the diaphragm and the passage of air from the sound into the retracted lung. As the respiratory oscillation in Dr. West's case was only half an inch during the first paracentesis this disturbing factor evidently did not come into play.—I am, Sirs, yours faithfully,

G. A. SUTHERLAND.

Old Cavendish-street, W., March 18th, 1895.

"THE RAM, THE BULL, AND THE HEAVENLY TWINS."

To the Editors of THE LANCET.

SIRS,—Referring to your Annotation with the above title, which appeared last week, I think the old theory as regards twin calves has been fairly established by modern experience—viz., that if the twins are of different sex the female is sterile though the oestrus and sexual instinct are generally present. Bewick, in his "History of Quadrupeds," 1800, mentions this as a well-authenticated fact and calls the female twin a "freemartin"—a term still used in many parts of the country. Stockbreeders who accept the theory are often unwilling to bring a sterile animal to maturity, whilst many to whom it is unknown overlook the matter altogether, so that extensive evidence is difficult to obtain. Two cases only have come under my own observation, and in each case the female twin proved sterile; but I have repeatedly seen twin calves of the same sex which have eventually both proved fertile. That no such law holds good as regards sheep or mankind is a matter of common knowledge.

I am, Sirs, yours faithfully,

Ballachulish, N.B., March 18th, 1895.

W. D. ANDERSON.

"THE REMUNERATION OF THE RESIDENT OFFICERS IN ST. BARTHOLOMEW'S HOSPITAL."

To the Editors of THE LANCET.

SIRS,—I do not quite understand the point at issue under this head, but as one who enjoyed the rare experience of a two years' service as house surgeon at this hospital (my

¹ Lung Elasticity in Health and Disease. Transactions of the Royal Medical and Chirurgical Society, vol. lix., 1876, p. 165.

colleague and friend, the late G. W. Callender, being the only other known to me) I feel it right to assert that 50 guineas were paid in each year to the surgeon under whom we served, and we received from the hospital 20 or 25 guineas per annum, with suitable rooms free. The three or four house surgeons had a housekeeper, and we each lived as we could afford. No doubt the hospital authorities made gain out of us, in addition to our services, by avoiding the payment of inquest fees, they themselves being the parish authorities. The information I derived during my house surgery under the late Mr. E. Stanley and Mr. E. A. Lloyd will ever be remembered with infinite pleasure, and the comparatively small honorarium paid to them will ever be considered a most trivial recognition of friendship.

I am, Sirs, your obedient servant,
North Cliff, Kidderminster, March 18th, 1895. S. STRETTON.

To the Editors of THE LANCET.

SIRS,—I still maintain that a man on the junior staff at St. Bartholomew's Hospital is not much, if at all, more out of pocket than a man on the junior staff of any other hospital with a school. Personally, I think that any resident officer ought to have rooms, commons, light, fire, and beer free during his term, and also a small salary to keep him in clothes and tobacco; but this does not alter my opinion as concerning the parallel between St. Bartholomew's and other hospitals with a school. Personally, too, I should say that the collegiate system ought to be much further carried out. At St. Bartholomew's certain idiotic restrictions that existed in my time at any rate ought to be done away with—perhaps they have been, and the "College" rebuilt. Perhaps when the long-pending removal of Christ's Hospital takes place we may see a collegiate establishment attached to the hospital on the model of one of the Oxford or Cambridge Colleges; but, with all its faults, St. Bartholomew's is a fine old place, and it is not seemly for a former resident to draw depreciatory comparisons between it and other hospitals after he has left.

I am, Sirs, yours faithfully,
AN OLD HOUSE SURGEON OF ST. BARTHOLOMEW'S.
March 19th, 1895.

* * This correspondence is now closed.—ED. L.

THE LONDON AND MANCHESTER INDUSTRIAL ASSURANCE COMPANY.

To the Editors of THE LANCET.

SIRS,—I think there must be many of your readers who will agree with me that something should be done to check the baneful influences that the London and Manchester Assurance Company is exercising towards the degradation of the profession amongst general practitioners. I suppose there is no legal reason why a medical man should not attend patients for the sum of twopence weekly, including medicine, if that is the amount of the remuneration at which he values his services, although such can hardly be said to raise the profession in the estimation of the public. But when it comes to touts annoying the patients of other practitioners by pestering them to join the society, I say that surely it is time that the bulk of the profession should by some means be able to stop such practices. The General Medical Council would hardly take action, I am afraid, were facts brought before them. The Medical Defence Union has, alas, its hands full with more legitimate work. I, therefore, appeal to the medical press to use its influence to restrain medical men from association with a society of this class. The South-West London Medical Society—to which I have the privilege to belong—lately passed a resolution condemning the practice of charging fees as low as one shilling or eightpence. Its members also passed, amongst others, the following by-law: "That no member of the society should solicit private practice either by public advertisement in the newspapers, by placards, by the public distribution of circulars, cards, or handbills, or by soliciting by agents." Other societies have formed similar by-laws.

I am, Sirs, your obedient servant,
Fulham, S.W., Feb. 25th, 1895. A GENERAL PRACTITIONER.

To the Editors of THE LANCET.

SIRS,—Will you kindly give expression of your opinion in your next issue of the above, in accordance with the orthodox views being presently held by leading members of the profession? Should it be supported by medical men upon the

principle of a company or aid association running medical business? Is it a burial club with medical aid thrown in at the expense of the profession? What are the abuses to which it is subject? Perhaps some members of the profession would give their experience upon the latter.

I am, Sirs, yours faithfully,

March 18th, 1895.

INQUIRER.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Health of Manchester during the last Quarter of 1894: the Medical Officer's Report.

THE births of 4000 children were registered within the city, and equalled an annual rate of 30·7 per 1000, against 32·4 the corrected average of the December quarters of the previous three years.

Of general sickness treated at the public hospitals and dispensaries there were 10,137 cases, or 780 per week, being an increase of 238 as compared with the last quarter of 1893; 1243 were treated as in-patients, 6718 as out-patients, and 2176 were visited at their own homes. Of infectious sickness 1025 cases were reported to the medical officer of health, against 852 in the preceding quarter, and 960 the average number for the fourth quarters of the previous three years. Severe cases of small-pox were reported during the quarter. In the last quarter of 1893 4 cases were reported, in the March quarter of 1894 there were 16, in the June quarter 195, in the September quarter 64, and, as has been seen, there were 7 only in the last quarter of 1894. In his report for the week ending March 9th Dr. Niven says that no fresh cases of small-pox have occurred here for the last nineteen weeks. Scarlet fever was notified in 725 cases last quarter, equal to an annual rate of 5·57 per 1000 persons living, against 4·25 in the immediately preceding quarter and 3·98 the average rate for the fourth quarters of the years 1891–93. In London the rate was 3·81 last quarter, and in the twelve selected notification towns in this part of England 4·42. In Halifax it was only 0·39, while in Warrington it was 9·50. Liverpool and Salford showed rates of 8·25 and 6·03 respectively. Diphtheria was slightly less prevalent than usual, 114 cases being reported, the average for the quarter being 130. In North Manchester the attacks corresponded to an annual rate of 1·50, in South Manchester of 1·03, and in the old unhealthy "township" it only equalled a rate of 0·71. There was less enteric fever than usual, 147 cases being reported, against 240 the average for the quarter. They were most numerous in the Manchester township, where the attack-rate equalled 1·34 per 1000, and fewest in North Manchester, which had a rate of 0·82, thus reversing their positions as to diphtheria. Whooping-cough and measles do not seem to have been excessively prevalent. In the course of the quarter the deaths of 2631 persons were reported, but after making allowance for the deaths of 70 non-residents this number is reduced to 2561. This equals a corrected annual rate of 19·7 per 1000. The average rate for the fourth quarter for the previous three years has been 23·6 per 1000, so that last quarter the rate was below the mean for the quarter by nearly 17 per cent. Here, again, the old township maintained its reputation, for the death-rate was equal to 24·7 per 1000, while in North Manchester it did not exceed 16·8. Last quarter was marked generally by a low death-rate—e.g., in the thirty-three great towns of the Registrar-General the rate was 17·7; in London 16·6; and in sixty-seven other large English towns with a population of about 3,500,000 the death-rate was 16·7, or 3·0 below Manchester. In Edinburgh it was 19·6, in Glasgow 21·6, and in Dublin 23·5. In rural England and Wales the rate was only 15·5.

Infantile mortality was lower than usual in Manchester. Measured by the proportion of deaths under one year to births registered, the rate last quarter was 162 per 1000, against 172 in the previous quarter, and 180 in the fourth quarter of 1893. North Manchester had the lowest rate, 140, while in the Manchester township it was 182. But according to Dr. Ashby of the Children's Hospital this high rate is much exceeded in certain areas.

In the decline of life, amongst those above the age of sixty-five the death-rate was high. 109·4 per 1000 living at that age, being equal to 98·4 per 1000 in North Manchester, while in the unhealthy district of the Manchester township it rose to 134·8.

Small-pox was the cause of death in one case last quarter, but no fresh cases have occurred for the last nineteen weeks. To the "seven principal zymotic diseases" 251 deaths were referred, equalling an annual rate of 1.93 per 1000 persons living, somewhat lower than the average for the fourth quarter. In the Manchester township it was 2.43 and in South Manchester 1.68 per 1000. The mortality from phthisis in the city generally was equal to 1.74 per 1000, ranging from 1.05 in North Manchester to 2.78 in the township. The deaths from diseases of the respiratory organs, exclusive of phthisis, corresponded to an annual rate of 4.79 per 1000, lower than the average for the quarter by 1.56. In North and South Manchester respectively the rates were 3.58 and 4.38; but in the Manchester township the rate was 6.55 per 1000.

Dr. Niven again regrets that in a population of upwards of half a million of people, "many of them living under notoriously unhealthy conditions, only 73 direct complaints should have been made to him during the last three months on matters concerning the public health." On the other hand, 1912 separate informations have been received from the chief constable, Mr. Malcolm Wood, showing what valuable services the police render, not only as regards the property, but the health of the community. With regard to the suppression of infection, 663 patients suffering from infectious diseases and badly isolated at home were removed to our local fever hospitals, 7790 infected articles of clothing were disinfected or burnt, 1552 rooms were fumigated, and the walls and ceilings of 1969 rooms were washed with a solution of chloride of lime and afterwards fumigated. By female district visitation 9934 "house-to-house" visits to poor people were paid during the last quarter; 540 special inquiries were made on behalf of the medical officer of health into cases of death; and 382 special reports were made to him on sanitary defects discovered in the course of daily visitation. Three districts, those of Deansgate, Chorlton South, and East Hulme, are at present unfortunately without female health visitors. The points specially noted are dilapidation, condition as to dirt or cleanliness, overcrowding, and the presence of sickness. As would be anticipated, two districts of the old township, Ancoats and the Central, are the worst in the city. Great disparity exists apparently in regard to the "incidence of sickness"; in the district of Angel Meadow only 4 per cent. of the houses contained sick inmates last quarter, while in West Hulme 59 per cent. were so circumstanced. Was it that in Angel Meadow the sick were generally taken to the hospitals, while in West Hulme they were treated at home? The average death-rate in the fifteen districts visited is much higher than that of the city generally, ranging from 25.1 in St. George's East to 50.9 in Angel Meadow. In West Hulme it is 34.7, showing that the low incidence of sickness in the former does not give an accurate notion of its salubrity.

The average weekly number of paupers relieved last quarter by the guardians of the Manchester township, which has an estimated population of 147,138, was 3872, of whom 3453 received in-door and 419 out-door relief, the numbers in the last quarter of 1893 being 3560 and 492 respectively. It must be remembered that the long and severe frost we have just passed through did not begin till quite the close of the year, and did not influence the amount of distress in the last quarter of 1894.

Influenza.

Manchester has not escaped the visitation in an epidemic form of this tantalising and too often fatal disease. So far, however, it has been of a milder type than in previous invasions. During the week ending March 2nd there were 5 deaths due to influenza complicated with some form of lung disease, and of these 3 occurred in the Manchester Workhouse. In the course of the next week, ending March 9th, the deaths assigned to it were 20, all the cases being of a complicated nature, and 9 of these occurred in the workhouse. In 2 other cases influenza was put down as a secondary cause of death. The medical officer of health has issued a placard containing "Precautions against Influenza," which has been extensively posted throughout the city.

Dr. Tatham's Report on the Health of Greater Manchester for the years 1891-92-93.

This report has been waited for with much interest and will repay not reading merely, but careful study. It is an example of statistical information only to be fully appreciated perhaps by experts; but even those of us who are not senior wranglers may gradually acquire confidence, for

the checks and counterpoises—the qualifying circumstances—are so carefully examined and allowed for that one feels safe in the guidance of a master who will keep clear of the pitfalls and fallacies that have led to the saying "figures will prove anything." Most interesting and ingenious are the applications of the Manchester life tables (which will long remain witnesses to Dr. Tatham's unwearied energy) to the various problems of vital statistics. Their practical value as supplying accurate tests of sanitary progress or regress is abundantly shown.

The Sanitary Inspectors' Association.

Mr. Francis Vacher, medical officer of health for Cheshire, read a paper on the Inspection of Food before the Sanitary Inspectors' Association at Manchester on March 16th. He said that horseflesh was sold as beef, but that no other deception of that nature appeared to be prevalent. The difference between the bones and fat of the ox and horse made it easy to distinguish the meat, and consequently it was usual to remove both the bones and the fat from horseflesh which was to be sold as beef. Various symptoms of disease and decomposition in the flesh of several animals were then described with a view to the recognition of unsoundness. Fashion had placed game in an exceptional position, and it was possible that an officer might not be supported by the magistrates in seizing it even when greatly decomposed. There appeared to be hardly any doubt that serious illness had been caused by eating oysters which had lain in water contaminated with sewage.

March 18th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Season's Epidemic.

AMONG various branches of the public service, the Postal employees appear to suffer much from illness. Of 1500, which comprises the whole of the Postal staff in this town, there are 115 on the sick list; these comprise 72 from the postal division and 43 from the telegraphic department. The majority of cases are ascribed to influenza; it is remarkable that the advent of any kind of ailment at the present time is readily classed under this cause.

Death under an Anæsthetic.

A man aged twenty-eight succumbed whilst under the influence of a mixture of chloroform and ether at the General Hospital on the 14th inst. He was the subject of empyema, and was about to be operated on when he suddenly stopped breathing. A necropsy revealed a dilated and feeble heart, and the verdict was given in accordance with the medical testimony, the coroner, Mr. Oliver Pemberton, remarking that the risk of anæsthetics was small, only 2 persons out of every 7000 anæsthetised meeting with death.

Suicides of Octogenarians.

An old man, aged eighty-one, was charged with attempting to commit suicide recently. The example of previous cases appears to have exercised some influence in this direction, since there have been in a short time four cases of men about the same age resorting to this method of terminating their days.

March 19th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Drunkenness in Newcastle-upon-Tyne.

THE Right Worshipful the Mayor, Alderman W. H. Stephenson, recently publicly stated that Newcastle was the most drunken town of its size in England, and he quoted official statistics in proof of his statement. The chief constable has just issued his report on the state of crime during the year 1894, in which the amount of drunkenness coming before the magistrates is dealt with. It appears that 6042 cases were investigated by the bench, being an increase of 703 cases over those of 1893; 1347 of these cases referred to non-residents of the city. The mayor has been roundly taken to task for his observations, but he maintains that his conclusions are correct, and certainly so far he seems to have the best of the argument. Why Newcastle should be more drunken than other similar towns it is

difficult to understand. The amount of serious crime in Newcastle is small. The chief constable says in his report "three-fourths of the crime of this country is occasioned by drunkenness." How does it happen that in the most drunken town in England the amount of serious crime is not larger than it is—is not in proportion to the amount of drunkenness? It is true nearly half the indictable offences in Newcastle are due to drink, and the proportion of indictable offences is high in Newcastle. It would seem to be a fair inference that while drink leads to the minor forms of crime, it is not the cause of serious crime—such, for instance, as that which came before the Lord Chief Justice at the late Liverpool Assize. From such serious crime Newcastle is, and always has been, remarkably free.

A Sidelight on Pauper Immigration.

For the sum of £37 10s. the master of the steamer *Palatine* contracted to bring from Alexandria to Boston thirty-eight Jews exiled from Russia. The contract was that the exiles should supply their own food on the voyage. After the vessel had been cleared the Jews came on board, and the vessel at once put to sea, on Jan. 31st, 1895. There was no accommodation of any kind for the Jewish party, which consisted of men, women, and children. They were to sleep on deck. The vessel was delayed on its passage by cold, wet weather, and the Jews were allowed to crawl into the coal bunkers, where they huddled together. The herrings and bread brought on board for the voyage by the miserable exiles were consumed, and only by purchase could food be obtained by the Jews, most of whom were destitute. Finally the party was landed at Boston, where no provision had been made for their arrival. It was stated during the investigation of this scandalous case before the magistrates at Newcastle-upon-Tyne, on March 19th, by the solicitor defending the master, "that there was a good deal of the same sort of thing carried on." The master was fined the full penalty, which, including costs, amounted to £81 8s. 9d., and an order against the ship was granted. This case throws a lurid light on pauper immigration and suggests many questions of national importance.

A Health Exhibition will be held in Newcastle from May 13th to June 11th next. The general object of the exhibition will be, as set forth in the promoters' prospectus, to make obvious the enormous strides made by sanitary science during the past twenty years.

Newcastle-upon-Tyne, March 20th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Health of Edinburgh.

THE influenza epidemic is waning, at least it is not so widespread. The death-rate, however, still keeps inordinately high, having reached 44 per 1000 last week. The intimations for the week included 5 fresh cases of small-pox, 52 of scarlet fever, and 435 of measles.

Close of the Winter Session in Edinburgh.

The medical classes in the University, the extra-mural school, and the women's colleges all close on Friday of this week. The session has probably been the longest on record, and it has on the whole been an uneventful one. The professional examinations in the University will begin next week.

The Aberdeen City Fever Hospital: Action against the Town Council.

A case was tried in the Court of Session, Edinburgh, before the Lord President and a jury, on the 26th and 27th ult., in which the pursuer, George Sutherland, claimed £500 damages in connexion with the death of his child in the Aberdeen City Hospital. The defenders were Mr. Gorman, one of the Aberdeen sanitary officers, and the Aberdeen town council. The jury gave a unanimous verdict for the defenders. As the case involves some important considerations relating to the laws of public health the charge by the Lord President to the jury has been printed in full by the Aberdeen town council as an appendix to the printed minutes and reports of their committees for the council meeting of March 18th. Considering the pursuer's position in life, the defenders did not ask for expenses, and besides defraying their own will have to pay the pursuer's taxed expenses.

March 19th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Outbreak of Influenza in Newry.

THERE has been quite an outbreak of influenza in epidemic form in Newry and district. The disease has broken out in the military barracks. Forty men have fallen victims to it. The hospital accommodation having been found inadequate several of the men are being treated in rooms allocated for the purpose. Fortunately, up to the present it is of a very mild type.

Professor Mahaffy.

It has been announced that the Senate of the University of Dublin will meet to-day, March 20th, at two o'clock, to elect a representative of Classis Secunda on the council in place of the Rev. Dr. Mahaffy, resigned.

The late Mr. C. H. Robinson.

At a recent meeting held by the proprietors of the late Ledwich School the following resolution was passed: "The proprietors of the late Ledwich School desire to offer to Mrs. Robinson and her family the expression of their sincere sympathy with them in their recent bereavement, and at the same time to place on record the sense of the great loss the proprietors have sustained by the recent death of their lamented and much-respected colleague."

Death of Mr. William Dyas.

It is with regret I have to announce the death of Mr. W. Dyas of Chicago, who met with a fatal accident by an incoming train on the Nickel-Plate-road, Chicago. William Dyas was born in Dublin on Nov. 4th, 1807. In his sixteenth year he entered Trinity College, Dublin. He graduated in 1830 at the Royal College of Surgeons in Ireland. In 1832 he received an appointment to the Cholera Hospital, county Kildare. Subsequently he was appointed Assistant Demonstrator of Anatomy at Trinity College, acting under Professor Harrison, of the University. In July, 1839, Mr. Dyas went to America and settled in Chicago, where for a time he acted as editor of the *Chicago Medical Journal*. He was eighty-seven years of age.

Simultaneous Ligation of the Subclavian and Carotid Arteries for Innominate Aneurysm.

An operation was performed by Mr. Coppinger at the Mater Misericordiae Hospital on Saturday which caused much interest and was witnessed by a large audience of surgeons as well as of students. The patient, a man aged thirty-five, suffered from a rapidly growing aneurysm of the innominate, projecting upwards above his sternum and clavicle, and causing severe pain and other pressure symptoms. The third stage of the right subclavian was encircled by a ligature, and the carotid at the seat of election similarly dealt with. The vessels were now tied, one immediately after the other, the ligatures being of silk. Aseptic precautions were rigidly carried out, all the dressings, iodoform, &c. having been previously sterilised by prolonged exposure to dry steam, after the von Bergmann method. The patient was not apparently a satisfactory subject for the operation, being short-necked and full-blooded. He, moreover, had suffered for some weeks from severe laryngeal symptoms, as well as from the so-called "vagus pneumonia" due to pressure on the recurrent laryngeal and trunk of pneumo-gastric nerves. I learn, however, that his temperature to-day (Wednesday) is normal, and that his progress is otherwise favourable.

The Protection of Infant Life.

The Dublin *Evening Echo* on Monday last contained an outspoken appeal for the alteration and amendment of the Burial Laws in Ireland. Under the various Acts for the registration of births and deaths in Ireland it is possible for interments to be made without a medical certificate as to the cause of death and even without registration. There are penalties, but they can be avoided; and it is the belief of our contemporary, and apparently a well-grounded belief, that this laxity has become a serious source of danger to child-life.

The Cork Ophthalmic Hospital.

The annual meeting of the subscribers to the Ophthalmic Hospital was held last week, and the report stated that in addition to the £4000 obtained by the late bazaar a further sum of £4000 was received in donations towards the building

fund. It was further stated that a site for the new hospital had been selected. Unfortunately, the proposed site met with anything but the unanimous approval of the subscribers present at the meeting. Lady Arnott led off the attack in a very vigorous speech. She pointed out that no exercise grounds would be available for the patients, and that tolerably close to the hospital would flow a stream from which at times are emitted certain malodorous fumes. Dr. Hobart, consulting surgeon, agreed with her ladyship as to the unsuitability of the site. On the other hand, Dr. Sandford, surgeon to the hospital, did not consider the position an insanitary one, and did not think they were likely to get a more suitable one. Many of the committee protested that the opposition to the site took them completely by surprise. Eventually the most sensible thing was done; the whole question was referred back to the committee, and as all concerned are actuated by a desire to do what will be best for the patients, I have no doubt a satisfactory solution will be soon arrived at.

Influenza at Cork.

Influenza has paid us an unwelcome visit, but so far it has not assumed a virulent type, though many of the cases are complicated by broncho-pneumonia. The city has been in a singularly healthy condition during the past two months, due, no doubt, to improved sanitation. In that connexion I may mention a fact of which our City Fathers are very proud. Domestic scavenging in Cork costs less than 1d. in the £, though Dublin citizens cannot have this done for less than 6½d. in the £.

Cork Lunatic Asylum.

A meeting of the board of governors of the Cork District Lunatic Asylum was held last week. The asylum contains at present 382 patients, while the estimated accommodation is 434. The hospital block, providing as it does most excellent accommodation for the treatment of the sick and infirm, has its utility greatly impaired by the want of a kitchen and by the loss of the infectious wing. Dr. Woods also brought under the consideration of the governors the advisability of increasing the medical staff as all authorities on asylum management now consider that there should be one medical officer for every 300 patients. The governors having gone very carefully and at great length into the subject, decided, on the motion of Alderman Dale, to approve of the addition being made to the medical staff, but that the extent of the increase should be left to a meeting of the full board to determine. The meeting then adjourned.

A woman named Stapleton has died at Carey's Road, Limerick, at the age of 102. Within a brief time before her death she enjoyed excellent health and was in full possession of her faculties.

March 20th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Uterine Tubal Pregnancy: Retention of Fœtus for Fifteen Years.

M. FOLET of Lille communicated to the Academy of Medicine on the 12th inst. details of the above extraordinary case. His patient is a woman now aged forty-nine years, who, having previously given birth to four children at full term, became, sixteen years ago, again pregnant. When the pregnancy had reached the ninth or the tenth month symptoms simulating labour occurred, blood and membranes being expelled, and the hæmorrhage persisting for six weeks. This strange occurrence led to the belief that no pregnancy had really existed. The abdomen remained, however, voluminous, but for fifteen years nothing further happened to disturb her until a year ago, when repeated attacks of peritonitis determined her admission into the Saint-Sauveur Hospital, Lille, where laparotomy was decided upon. The operation was laborious on account of the presence of numerous adhesions of the foetal sac to the intestines. The sac was, nevertheless, excised almost entire, the too adherent fundus only being left *in situ* and stitched *en colerette* to the lower part of the abdominal incision. Recovery was complete in six weeks, no accident having occurred to retard it. The sac contained two fœtuses—one which had at its death attained the age of two or three months, and the other which had reached the full term of nine months—a phenomenon which is so extremely rare in tubal gestation that only six or seven examples are recorded. The fœtus exhibited at the Academy

by M. Folet was not a lithopædion. Its tissues were supple, non-calcified, but were, nevertheless, as dense as cooked bacon. With the exception of certain alterations undergone, the tissues had retained their structure recognisable by the naked eye and under the microscope. The peculiar lardaceous degeneration above mentioned will be further investigated by Dr. Curtis, *professeur-agrégé* of Pathological Anatomy at the Lille Faculty.

The War against Alcoholism in France.

The Conseil Supérieur de l'Assistance Publique, having at the request of the Government deliberated over the advisability of establishing special retreats for the treatment of lunacy caused by alcoholic abuse, has sent in the following report, which I transcribe textually: "1. Que le gouvernement encourage la création d'établissements spéciaux pour les aliénés alcooliques et l'organisation de quartiers spéciaux dans les asiles. 2. Qu'une application plus rigoureuse soit faite des lois contre l'ivresse publique. Le Conseil Supérieur signale, en outre, aux pouvoirs publics l'utilité plus grande et plus pressante encore de rechercher et d'appliquer les moyens de prévenir l'alcoolisme."

March 19th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Meeting of the German Balneologists.

THE German Balneological Society held its annual meeting in Berlin from March 7th to 12th, Professor Liebreich presiding. In his inaugural address the president said that many valuable improvements in therapeutics had originated from this society. He mentioned especially the fresh-air treatment of tuberculosis introduced by the late Dr. Brehmer at Görbersdorf, which had up to now given the best results in this dreadful disease. In that society it would be unnecessary to state that pulmonary tuberculosis is not merely an infectious disease, but depends also upon the social condition of the population. Fresh air and good food have contributed more to the cure of sufferers than tuberculin and the other antitoxins invented by bacteriologists. Professor Litten then read a paper upon the Diaphragm Phenomenon. He has found that the movements of the diaphragm during respiration can be seen through the walls of the thorax and abdomen if the patient lies on his back near a window so that his body has full light on it. Under these circumstances one sees through the skin a kind of undulation descending with the inspiration from the sixth intercostal space down to the ninth rib, and sometimes to the costal arch, and ascending again with the expiration. Professor Litten pointed out the great importance of this phenomenon in cases of emphysema, pleurisy, &c., where the respiratory power of the lungs can be estimated from the extent of the above-mentioned undulation. Dr. Grödel of Naheim then spoke on the Hydropathic Treatment of Arterio-sclerosis. He said that it is an error to say that hot baths would be harmful to such patients, although as a rule they are more than fifty years old. Although he had often ordered baths of 35° C. he had never seen apoplectic attacks during or after the bath. He advises his patients to stay only for five minutes in the bath and to put a cold compress on the head in order to remove the blood from the brain. Diseases of the heart took a considerable place in this year's proceeding. Professor Kisch (Marienbad) read a paper on Cardiac Irregularity caused by General Obesity, and Dr. Pospischill on the Hydrotherapy of Organic Heart Diseases. The latter mentioned the efficacy of this method, even in an advanced stage of the illness. The hydrotherapeutic treatment, he said, regulates the cardiac action, repairs the elasticity of the bloodvessels, and strengthens the heart muscle. Every form of heart disease is fit for this treatment, which can be performed not only in hospitals but also in the homes of the poor. A very interesting paper was that of Dr. Fürst (Berlin) on Inhalations at the Seaside. The good results obtained in cases of scrofulosis by inhalations of salt air in the salt-pits have induced him to try the same method at the seaside. For this purpose he proposes to build open halls to which the sea-water will be conducted in pipes and dispersed by an engine. In this way the air becomes mixed with the sea water, and the children who have to stay in the hall for several hours inhale an air

which contains a great percentage of salt. Dr. Lindemann of Hallgoland approved Dr. Fürst's proposition, and remarked that his method would be useful also for patients suffering from chronic laryngitis. The meeting finally discussed the hygienic condition of the health resorts. A committee was elected, which made the following propositions. The municipal authorities of the health resorts should be asked to provide—(1) an efficient supply of good drinking water by aid of water-works; (2) arrangements for artificial ice; (3) hospitals for infectious diseases; (4) establishments for the disinfection of goods &c.; and (5) public mortuaries. Dr. Ibell (Ems) proposed that every health resort should appoint a hygienic council of which at least one resident medical man should be a member. The propositions were unanimously adopted and the meeting then closed.

Curious Evidence of a Medical Officer.

A man who was brought before a jury of Berlin had promised a woman in the latest stage of tuberculosis to cure her within three months. He had ordered her a medicine for which he charged twelve marks, the real worth being only twenty pfennigs. A fortnight afterwards the patient died, and her family indicted the quack for fraud. At the trial Dr. Long, medical officer at the Berlin law courts, was asked by the defendant's counsel if it was not possible to cure "consumption." Dr. Long answered that it would be as easy to fetch a star from the sky as to find a universal remedy for this illness. The defendant's counsel asserted that his client was as persuaded of the curative effect of his remedy as Professor Koch was of tuberculin, and could, therefore, not be made responsible because it was a failure. Dr. Long answered that in his opinion they were, both Dr. Koch and the defendant, guilty of the same crime, and he did not understand the public attorney only prosecuting the little and not also the great thieves. This allusion caused the utmost sensation in the court. The judge said he was sorry he must blame Dr. Long for comparing a scientific authority like Professor Koch with a quack. The defendant was condemned to three months' imprisonment.

March 18th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Cases of Homicidal Mania.

HOMICIDAL mania has been assuming epidemic proportions in our hospitals, particularly in our lunatic asylums. In the Santo Spirito a nun of exemplary character and high professional worth was assassinated by a patient who owed her a quite imaginary grudge, and just the other day one of the most prominent of our citizens—a man respected and beloved throughout Italy, the Marchese Berardi—was brutally murdered in open day in the villa annexed to the Manicomio. As one of those officially interested in the asylum the Marchese was on duty, superintending a group of labourers employed in removing earth from the airing grounds, and he was just in the act of suggesting to a subordinate the propriety of laying a small *binario* (pair of rails) to facilitate the carting away of rubbish when he was suddenly assailed from behind by one of the labourers aforesaid. This man, who as a non-violent patient had been allowed to work in the open, dealt him with uplifted spade a murderous blow on the occiput, felling him to the ground. Bleeding profusely and absolutely unconscious, the Marchese, after the first hasty attentions of the resident physicians, was taken to one of the houses of which the villa is composed and was soon afterwards examined by Professor Paolo Postemski, who holds one of the chairs of Surgery in the Roman school. Trephining was at once performed, and in half an hour, during which he was assisted by Professors Bertini and Scalzi, Professor Postemski was able to give the following account of the injury: "Depression of the right parieto-occipital region, with fracture external to the depression. Fracture of the internal surface and disintegration of the cerebral substance. Subdural hæmorrhage. Probable fracture of the base of the skull. Prognosis very grave." His Excellency Dr. Baccelli arrived just as Professor Postemski was penning the last words of the bulletin, and, having heard the particulars, approved of the operation and also confirmed the very unhopeful prognosis. The Marchese never recovered con-

sciousness, but lingered on till a little past midnight, when he expired. Meanwhile his assassin, who had been put under arrest, was examined and the following instructive history was elicited. He is a young man, Bruni by name, some twenty-seven years of age, and a Sabine by birth. He is of middle height, blonde of complexion, and with a prepossessing type of countenance. Of unknown parentage, he was brought up to an uncertain mode of life, working at odd jobs, till the age of nineteen, when he was sentenced to seven months' imprisonment for cutting and wounding, after which he underwent another term of incarceration for theft. In August of 1888 he entered as a conscript the 15th Regiment of Infantry, and about the close of his period of service he insulted and attacked his superior officer. Put on his trial he was found to be insane and shut up in the lunatic asylum. From this he was unaccountably set at liberty—unaccountably, I say, for the report of the resident physicians, dated 1892, was to this effect: "Alienazione cessata; persistente semi-imbecillità" (alienation ceased; persistent semi-imbecility). The latter condition ought certainly to have caused some kind of surveillance to be kept over him; but no. Set at liberty, as I have said, he soon gave symptoms of a recrudescence of his malady, so that for violent conduct in the Piazza del Popolo he was taken into custody by the Carabinieri, and his mental alienation having been once more duly certified he was again shut up in the lunatic asylum. Here he developed the so-called "persecution mania," and at first had to be safeguarded among those classed as "agitati" (violent). But in October last, having till then maintained a persistent calm, he was relegated to the class of "paranoici tranquilli" (peaceable lunatics) and employed, as we have seen, in rural labour. Interrogated by the director of the asylum, Professor Bonfigli, and the Questor, Signor Sironi, as to what induced him to attack the Marchese Berardi, he replied: "I had condemned the Marchese to death because once he had complained of my work." Successive interrogations elicited little more than this, that he was constantly being persecuted by "pezzi grossi"—personages in authority—among whom he classed "Cabinet Ministers, colonels, majors, and presidents," and added that he struck down the Marchese Berardi as one of those persecutors. And so he stuck to his text, till Professor Bonfigli and Signor Sironi made up their minds as to his case and relegated him to the class of the "agitati," taking the precaution (his menacing looks and language considered) to put him in a "camicia di forza" (strait-waistcoat). I need pursue the matter no further, except to add that about the same time another deed of violence was committed in the same asylum by one of the patients (an epileptic) dealing another of the same class a murderous kick on the abdomen, the result of which was death some hours afterwards.

The Management of the Manicomio.

A few comments will be in place as to the circumstances under which the Roman Manicomio has had to register such tragedies and the system under which these become possible. In some respects it has a record as honourable as any in Europe. It was one of the first on the Continent to adopt the non-restraint system inaugurated by Tuke. Thanks to its enlightened patron, the late Pope Pio Nono, the "bath of surprise," the shackles, the strait-waistcoat, and such like were either wholly done away with or had recourse to only under rare and special circumstances. The "out-door employment" system was freely introduced, and under such excellent superintendents as Dr. Viale Prelli and, more recently, Dr. Fioridispini the beautiful villas on the Janiculum were laid out for the reception of non-violent cases whose time (if paying patients) could be occupied in such intellectual or artistic pursuits as were congenial to them, or (if of the poorer or pauper class) by labour, agricultural or other. Repeated visits to this really delightful retreat convinced me of the thoroughness with which the non-restraint system had been carried out, and, on the whole, the success which had crowned it. But one defect always struck me, and not me only, but others who were admitted on the visiting list. That was, according to our British ideas, the insufficiency of attendants. Those who were on duty seemed in the highest degree capable; but they were inadequately supported. Now, if there is a *conditio sine qua non* which, more than another, must be enforced in the treatment of lunatics it is this, that "the sense of being controlled" should never be absent from them. An over-awing

demonstration of surveillance is not absolutely necessary. It will be enough if the patient feels that, even in non-official garb, there are attendants who have their eye on him, and who are ready (reinforced at once, if need be, by others) to check any outbreak on his part. Just as on the high seas the man-of-war least often suffers shipwreck from its greater supply of hands, so in the lunatic asylum casualties are fewest where attendants, *en évidence* or in the background, are most in readiness. Now in the Roman Manicomio this chronic defect had been aggravated by recent administration. According to its most able and efficient superintendent, Professor Bonfigli, it is a fact that no fewer than thirty among the "sorveglianti" and "infermieri" (keepers and male attendants) had, for a temporary cause, been dismissed—some of them had been on the staff of the Manicomio for over twenty years—and that, at the time of the recent murderous outbreaks among the patients, the *personnel* was dangerously undermanned. It is said that the author of this proceeding was no other than the Marchese Berardi himself. If so, that estimable man has expiated by nothing less than his life an error in administration which, in hot-blooded populations generally, and particularly in their lunatic asylums, can never be committed with impunity.

March 16th.

Obituary.

LOUIS FLORENTIN CALMEIL, M.D.

OUR Paris correspondent writes:—"The survival up to the 11th inst. of the famous alienist will come as a surprise to the majority of those of your readers who are interested in mental medicine. This surprise will be fully justified when on turning to the chapter on general paralysis of the insane in physiological works we read such sentences as the following:—'This interesting but hopeless form of disease may be said to have been unknown until it was fully described in the admirable *mémoire* published by Calmeil in 1826. In his later work, "*Traité des Maladies Inflammatoires du Cerveau*," 1859, he designates the disease "*Periencephalitis chronica diffusa*.'" Again, 'In 1826 M. Calmeil gave a most complete account of it, and to him frequently is ascribed the merit of having been the discoverer.' Louis Florentin Calmeil, the *doyen* of French alienists, was born on Aug. 9th, 1798; he was, consequently, at his death in his ninety-seventh year. His father, a retired barrister, renounced practice early in his career and took up his residence at his country house at d'Yversay in Poitou. Here was born his third son, who was destined to become so famous as a 'mad doctor.' At the age of nine years he and an elder brother were placed in a house at Poitiers under the care of a trusted servant in order to pursue their classical education. He soon evinced a passionate liking for natural science. One day he informed his professor that he intended being a botanist, which infantile resolution did not prevent his being entered later as a student in the *École Préparatoire de Médecine de Poitiers*. While there he daily repaired to the hospital, where he soon became an assiduous attendant in the post-mortem room. Every spare moment he devoted to the study of plants and insects. The inevitable removal to Paris came in due time. In this new sphere his untiring industry quickly procured him the place of *externe des hôpitaux*. In this quality he was a frequenter of Dupuytren's wards. One day, carried away by a too close attention to the illustrious surgeon's utterances, he accidentally touched the bed of a patient who had just been operated on. Dupuytren thereupon seized him by the arm and shook him so violently that, terrified at such treatment, he procured his mutation to the Salpêtrière, where he worked under Rostan. This good-natured physician took a great fancy to young Calmeil and engaged him to take numerous notes of cases of partial softening of the brain. Appointed *interne*, he was sent to Charenton under Royer-Collard. He was then twenty-four years old, and he never left that hospital until fifty more years had elapsed. There he passed all his life—a life of devotion to his poor patients and to his researches into the nature of their diseases. The death of his loved master, Royer-Collard, deprived him of an influential friend; but he found in his successor, Esquirol, an equally ardent supporter. Calmeil became his right-hand man. Knowing that his *protégé* had during his sojourn at the

Salpêtrière made a special study of hysteria and epilepsy, Esquirol requested him to write a *mémoire* embodying his observations. The task accomplished, Esquirol entered the *mémoire* for a prize he himself had founded. Félix Voisin and Calmeil were bracketed equal and shared the prize. Esquirol had frequently urged his master Pinel to found a private paying asylum, but the latter, pleading the infirmities of old age, persuaded his pupil to put the idea into practice. Calmeil entered with enthusiasm into the organisation of this new scheme; but when, later, Esquirol wished him to become his partner in the venture, he firmly declined in these words: 'Non, je n'accepte pas, car non-seulement je m'y ruinerais, mais, ce qui est pire, j'aurais ruiné mes co-associés. J'ai mon plan tout tracé et bien arrêté; je ne veux que le travail avec l'indépendance.' This disinterested programme he followed to the letter. His duties over, he would retire to a modest pavilion he called his hut, when after a few hours' sleep he would, winter and summer, wake before sunrise to write the works which have placed his name on the roll of honour as a psychologist. Appointed Inspector of Charenton, then Assistant Physician, he obtained the unsolicited distinction of the Cross of the Legion of Honour. At the death of Esquirol he was deemed by his *confrères* the best fitted to succeed him as *Médecin-en-chef*. But royal favour procured the post for another, and Calmeil continued his studies until 1848, when, terrified by the Revolution, his chief fled, and a vacancy was once more declared. This time Calmeil was more fortunate, being appointed to the female wards, while the men were placed under the care of Archambault. Soon after, his coadjutor having to retire, he was appointed *Médecin-en-chef*, a post he held for twenty-two years. In the accomplishment of his responsible duties he was ever gentle and dignified towards his pupils and subordinates, and most patient with his poor charges. It was during his tenure of the Physicianship-in-chief that he crowned his work by the publication of his treatise '*Maladies Inflammatoires du Cerveau*.' This procured him promotion (to office) in the Legion of Honour. In 1872 Calmeil asked to be allowed to retire. He chose Fontenay-sous-Bois, in the Charenton district, as the place wherein to pass the evening of his life. Here in a pretty villa built specially for him, and which his friends and admirers christened 'La Maison du Sage,' he gave himself up to his favourite botanical studies and to his book and the notes he had accumulated during his sojourn at Charenton. Nothing delighted him more than a visit from some old pupil, become since famous perhaps. For some years past, senile weakness, while sparing his intellect, had deprived him of the strength necessary to enable him to take his favourite walks in the Vincennes woods, or in his garden. I append a list of his principal works, some of which are undoubtedly standard productions:—'*De l'Épilepsie étudiée sous le rapport de son Siège et de son Influence sur la Production d'Aliénation Mentale*' (Thèse, 17 juin, 1824); '*De la Paralyse considérée chez les Aliénés*' (Paris, 1826, 8vo); '*Des Maladies de la Moelle Epinière*' (Paris, 1839, 8vo); '*De la Folie considérée sous le point de vue pathologique, philosophique, historique, et judiciaire, depuis la Renaissance des Sciences en Europe jusqu'au XIX^e Siècle, (descriptions des grandes épidémies de délire simple ou compliqué qui ont atteint la population d'autrefois et régné dans les monastères; exposé des condamnations auxquelles la folie méconnue a souvent donné lieu; Paris, 1845, 2 vols. 8vo); 'Traité des Maladies inflammatoires du Cerveau' (ou histoire anatomopathologique des congestions encéphaliques, du délire aigu, de la paralysie générale ou péri-encéphalite diffuse, à l'état simple ou compliqué, du ramollissement cérébral local aigu et chronique, de l'hémorragie cérébrale localisée récente ou non récente; Paris, 1859, 2 vols. 8vo); 'Du Ramollissement partiel du Cerveau (par Rostan; Obs. par Calmeil). One of the first to utilise the microscope in the study of mental derangements, he always betrayed satisfaction at the improvement effected in an instrument which he prophesied 'would render great service in this particular branch of medicine. Ever a most conscientious student, he would often allow years to elapse before he would publish communications of the correctness of which he was not absolutely sure. He thoroughly believed that every neurosis or form of lunacy corresponded to a definite lesion which it behoved the student to discover. His name will for ever remain associated with the disease, general paralysis of the insane, which he succeeded in establishing as a clinical and pathological entity. Although a member of the Société Médico-Psychologique, he rarely*

attended the meetings, preferring to remain at Charenton amongst his books and patients. In Calmeil we may salute a man who lived all his days a true student—disinterested, modest, and consequently great. I feel that these few commemorative words give but a dim picture of such a personality, but I venture to hope that their perusal will not be found uninteresting."

WILLIAM BOYLE COGHLAN, M.A., M.D. Q.U.I.,
M.R.C.S. ENG.

GENERAL regret has been occasioned among a wide circle of friends by the death of this popular and highly respected gentleman, who passed away on March 8th at his residence in York-place, Oxford-street, Manchester. He was born in county Cork about sixty-six years ago, and was the first scholar in Queen's College, Cork. He subsequently studied divinity, and having graduated in 1853 as M.A. at Trinity College, Dublin, he became curate of Chirbury Parish Church, in Shropshire, as mentioned in our columns last week. Having unhappily lost his voice, he obtained permission from his ecclesiastical superiors to enter the medical profession, and qualified himself for this new career by studying at his old university and at St. Thomas's Hospital. In 1864 he became a Member of the Royal College of Surgeons of England, and in 1868 he graduated as M.D., eventually settling in practice in Manchester. He nevertheless was able to continue his pulpit ministrations, and was well known and highly esteemed as a preacher in many churches of the city and suburbs.

EVAN PIERCE, M.D. ST. AND., F.R.C.S. EDIN.,
L.F.P.S. GLASG., L.S.A., J.P.

By the death of Dr. Evan Pierce, who passed away at his residence in Denbigh on March 15th, the profession of medicine in North Wales loses one of its best-known exponents. Dr. Pierce was born in 1808 in a farmhouse a few miles from Denbigh, and on leaving school commenced his medical education by apprenticeship to Drs. Yorke-Jones and Lodge of Denbigh. He subsequently studied in the medical schools of London, Edinburgh, and Paris, and in 1836 gained the diploma at the Royal College of Surgeons of Edinburgh, the Faculty of Physicians and Surgeons of Glasgow, and the Apothecaries' Society of London. In 1832, while a student at Edinburgh University, the young Welshman distinguished himself by his active participation in the work of the cholera hospitals in Edinburgh and Musselburgh. Returning to his home in Denbigh he found that the same epidemic was prevailing there, and that the mortality was very heavy. His services to his native place on this occasion were remarkable, and were publicly acknowledged by his being presented with an oil painting of himself. Having subsequently settled in practice in Denbigh, he speedily attained success, and in 1844 graduated as M.D. at the University of St. Andrews. About the same time he became a member of the Denbigh town council and in 1866 was elected mayor, an office which he held for five years in succession. In 1848 he became coroner for Denbighshire, and retained the appointment up to the time of his death. In this capacity he had to hold the inquest on the victims of the Abergele accident on the London and North-Western Railway in 1868, when more than thirty lives were lost, partly through the collision and partly through the ignition of mineral oil with which a truck was loaded. He was a public benefactor to his town, for he supported a hospital of fifteen beds, and presented to the borough a public pleasure ground and a public hall, acts of munificence which involved an outlay of several thousand pounds. In commemoration of his mayoralty the townspeople in 1875 erected in the pleasure ground a limestone column seventy-three feet in height, surmounted by a statue of him in white marble. He was remarkably devoted to field sports as long as his bodily energy permitted, and was in every respect a staunch Welshman.

JOHN BALBIRNIE, M.A., M.D. GLASG.

WE regret to announce the death of Dr. Balbirnie, which took place on March 11th at Keyworth, near Plumtree, Nottinghamshire, as the result of an attack of influenza. He was a man of much culture and literary ability, and some

forty years ago gained a considerable reputation as a writer on medical subjects, principally in connexion with hydro-pathy. Born in Glasgow in 1810, he in due course entered the arts classes of the University there, graduating as M.A. in 1830. His tendency being towards the medical profession, he continued his studies in this direction at the same school, eventually taking the M.D. degree in 1836. Previously to graduation he spent some time in improving himself by observing the practice at the great medical schools in Paris, and this, no doubt, partly accounted for the fact that at Glasgow University he gained the Brisbane Bursary of £200 awarded to the most meritorious of the theses presented by the medical graduates of the year. Balbirnie on this occasion took as his subject "The Speculum applied to Organic Diseases of the Uterus and its Appendages." His best-known work was probably "The Water Cure in Consumption and Scrofula," published in 1854. He had, however, previously brought out "The Philosophy of the Water Cure" in 1845, and in 1863 he wrote "The Physiological Basis and Curative Effects of the Turkish Bath." His last work appeared in 1870 on "Inhalation as a Branch of Scientific Therapeutics and a new Apparatus for giving it Effect." Dr. Balbirnie practised in various towns in England and Scotland; a great part, however, of his long life was spent in Sheffield. Keyworth, where he died, had been his residence for the last seven years. He has left two sons, both of whom are in the medical profession.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Waldau of Berlin, one of A. von Graefe's earliest assistants.—Dr. Marjolin, honorary surgeon to the Paris hospitals.—Dr. Larabrie, Professor of Clinical Surgery in Nantes.—Dr. F. R. Müller, formerly President of the Swiss Federal Medical Examination Commission.—Dr. A. Beketoff, formerly Professor of Surgery in the University of Kazan.—Dr. Bruno Mester, first assistant in the Breslau Medical Clinic, at the age of thirty-one.—Dr. F. W. Lorinser, formerly President of the Council of Hygiene of Lower Austria.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Florence*: Dr. Tamburini of Modena has been appointed Professor of Clinical Psychiatics. Dr. Roster has been promoted to the Ordinary Professorship of Hygiene.—*Jena*: Dr. H. Haeckel, *privat-docent* in Surgery, has been appointed Professor.—*Lyons*: Dr. Augagneur has been appointed Professor of External Pathology.—*Pavia*: Dr. Mangiagalli of Catania has been appointed Professor of Midwifery and Gynecology.—*Naples*: Dr. Pedicini has been recognised as *privat-docent* in Medical Pathology, and Dr. Farena as *privat-docent* in Medical Chemistry.—*Prague (German University)*: Dr. Wölfler of Gratz has been appointed to the chair of Clinical Surgery in succession to Dr. Gussenbauer. *Bohemian University*: Dr. Pesina has been recognised as *privat-docent* in Pathology and Therapeutics.—*Vienna*: Dr. Julius Schnitzler has been recognised as *privat-docent* in Surgery.

THE St. Patrick's Festival Dinner of the Irish Medical Schools' and Graduates' Association was held on St. Patrick's Eve, March 16th, at the Café Monaco, Dr. H. Phillips-Conn, President of the Association, being in the chair. Among those present were Sir William MacCormac, Sir B. W. Richardson, Dr. Clement Godson, Dr. Gilbert Smith, Mr. Keetley, and Mr. Edmund Owen. There were also a number of ladies present. Songs were sung and national airs played on the Irish pipes.

ROYAL INSTITUTION.—Among the Lecture Arrangements after Easter we notice the following:—Professor George Forbes, three lectures on Alternating and Interrupted Electric Currents; Professor E. Ray Lankester, F.R.S., four lectures on Thirty Years' Progress in Biological Science; Professor Dewar, F.R.S., four lectures on the Liquefaction of Gases; and Dr. William Huggins, F.R.S., three lectures on the Instruments and Methods of Spectroscopic Astronomy (the Tyndall Lectures). The Friday evening meetings will be resumed on April 26th, when a discourse will be given by Dr. John Hopkinson, on the Effects of Electric Currents in Iron on its Magnetisation.

DENTAL HOSPITAL OF LONDON.—Mr. Henry Harben, J.P., has, in addition to £500 already contributed by him, promised a further munificent donation of £1000 towards the amount required for building the new Dental Hospital in Leicester-square, conditionally upon a sum of £13,000 being contributed by the public within reasonable time so as to enable the committee to commence the building.

BEQUESTS AND DONATIONS TO HOSPITALS.—The governors and directors of the Bank of England and Mr. Richard Benyon have respectively sent a donation of £100 to the Metropolitan Hospital, Kingsland-road.—A Retford lady has anonymously given £100 to the Retford Cottage Hospital for surgical purposes.—The collections for the local medical charities for the year 1894 of the workpeople of Messrs. J. S. Fry and Sons, Bristol, amounted to £502 6s. Of this sum £115 each were apportioned to the Bristol Royal Infirmary and General Hospitals and £189 10s. to the Bristol Dispensary.—The late Mr. Robert Smith, of the firm of Smith, Payne, and Smith, bankers, London, has bequeathed £500 to the Hertford Infirmary.—The late Mrs. Church Dixon has bequeathed £500 (free of legacy duty) to the general funds of the Belgrave Hospital for Children, Gloucester-street, London.—The board of management of the British Home for Incurables has received a contribution of £300 in memory of the Rev. W. Heygate Benn; and Mr. H. C. Hartley has also sent to the Home a donation of £150.—The late Mr. C. W. Savage of Westbury-upon-Trym has bequeathed £200 each to the Bristol General Hospital and the Bristol Royal Infirmary, and £100 each to the Children's Hospital and British Eye Hospital.—The late Mr. W. F. Rawdon, of Clifton, York, has bequeathed £1000 each to the Middlesex Hospital (Female Cancer Ward) and the York Hospital, and £2000 to the York Dispensary.—Mrs. James Packe has sent a donation of £500 to the funds of Queen Charlotte's Lying-in Hospital, Marylebone road, London.—An anonymous donor has sent a donation of 300 guineas to the Royal Hospital for Diseases of the Chest, City-road, London.—The late Mr. J. H. Worth of Retford has bequeathed £100 (free of legacy duty) to the Retford Dispensary and Cottage Hospital.—Lady Kortright of Roden House, Brentwood, has sent a donation of £7000 to the Grosvenor Hospital for Women and Children, Vincent-square, Westminster, in aid of the building fund.—Mr. Herbert H. Sharland, late of Thavies-inn, Holborn, London, has bequeathed £1000 each to the North Devon Infirmary (Barnstaple), St. Luke's Hospital, Old-street, London, Guy's Hospital, St. Thomas's Hospital, the Royal Free Hospital (Gray's-inn-road), the Hospital for Sick Children (Great Ormond-street, Bloomsbury), and the Royal Albert Orphan Asylum, and £200 to the Barnstaple Dispensary.—The late Mr. John H. Brain Kenridge of Chew Magna, Somersetshire, has bequeathed £200 to the Bristol Royal Infirmary and £100 to the Bristol General Hospital.—The late Mr. James Price, of Barcombe, Paignton, Devon, has bequeathed £1000 each to Guy's Hospital, St. Thomas's Hospital, St. George's Hospital, Charing-cross Hospital, the London Hospital, the Westminster, King's College, Middlesex, and the Royal Free Hospitals, the North London or University College Hospital, and the Royal Hospital for Incurables, West Putney, and £500 each to the Brompton Cancer Hospital and the Torbay Infirmary at Torquay. The testator also bequeaths £1000 each to the Liverpool Infirmary, the Liverpool Northern Hospital, the Liverpool Southern Hospital, and the Dispensaries at Liverpool.—The following donations have been made to the special fund now being raised for St. Thomas's Hospital, London:—The Directors of the Bank of England, 500 guineas; Messrs. Barclay and Perkins, £1000; the Cannon Brewery Company, London, 100 guineas. The London City Companies have contributed to the same fund as follows: the Mercers' Company, 500 guineas; the Clothworkers' Company, £500; the Grocers' Company, £250; the Leather-sellers' Company, 200 guineas; the Drapers' Company, 100 guineas; the Carpenters' Company, 100 guineas; and the Salters' Company, 100 guineas.—The Mercers' Company has voted a grant of 50 guineas to the Surgical Aid Society (offices, Salisbury-square, London).—The Fishmongers' Company has granted £50 guineas to the East London Hospital for Children, Shadwell, E.—The Leather-sellers' Company has sent a donation of 50 guineas to Guy's Hospital.—The Goldsmiths' Company has voted £200 to Guy's Hospital and £100 to the North-Eastern Hospital for Children, Shoreditch.

At the meeting of the Royal Society on Thursday, March 14th, Professor Engelmann of Utrecht delivered the Croonian Lecture on the Nature of Muscular Contraction.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 6th, Dr. J. S. Tew, President, being in the chair.—Mr. Anderson read a paper on Some Cases of Renal Surgery, and detailed six cases in which nephro-lithotomy had been performed, and six of nephrorrhaphy. In one of the former a large branched stone was removed from the right kidney, and a small one from the left ureter by extra-peritoneal ureterotomy. All the cases recovered. Of the nephrorrhaphies two were of recent date and the ultimate result could not be recorded, but the remaining four had been entirely relieved of their symptoms, the kidneys remaining fixed.—The President and Dr. Cattle, Mr. Tompsett, Dr. Watson, and Dr. Tresidder took part in the discussion of the subject, and Mr. Anderson replied.

ROYAL HOSPITAL FOR CHILDREN AND WOMEN.—The annual meeting of this hospital was held at the Mansion House on March 15th, the Rev. Arthur Powell (chaplain) presiding, in the absence of the Lord Mayor, who was unfortunately prevented by illness from being present. The Lady Mayoress, however, was among the company. The in-patients treated during the year were 591, and the attendances of out-patients exceeded 32,000. The financial position of the hospital was far from satisfactory. Invested capital to the amount of £750 had to be realised in order to meet current expenses, and there nevertheless remained liabilities of about £260. An earnest appeal for aid was made to the public, especially to the merchants and bankers of the City, the hospital having been originally established in the City and removed to its present position in Waterloo-road only in 1825.

PRESENTATION.—Mrs. Agnes N. Hicks of Tad-dington, Dunstable, Bedfordshire, has been presented, as a memorial of her late husband, Dr. Charles C. Hicks, of Wokingham, with a beautiful carriage clock, bearing this inscription: "To the memory of the late Dr. Hicks, from the poor of Finchampstead." An illuminated framed address was at the same time presented, of which the following is a copy: "Presented to the widow and son of the late Charles Cyril Hicks, M.D., with timepiece. 'We, the undersigned, representing the poorer inhabitants of Finchampstead, request your acceptance of the accompanying testimonial to the memory of the late Dr. C. C. Hicks, as a slight token and acknowledgment of his unwearied and self-denying labours amongst us during his fourteen years of devoted service as a medical officer, February, 1895.'"

BRISTOL HOSPITAL FOR SICK CHILDREN AND WOMEN.—The annual meeting of this institution was held on March 16th at the hospital buildings, St. Michael's-hill, Bristol, the High Sheriff presiding. The report showed that 918 children and 40 women had been admitted as in-patients during 1894, while the attendances of out-patient children amounted to 23,000, and of women to 14,000. The hospital has a measles ward, to which 62 children were admitted; among these there were 8 fatal cases, of whom 7 were aged two years and under. The finances of the institution are fairly satisfactory, the receipts for the past year having slightly exceeded the ordinary expenditure. Six legacies were received, amounting to a total sum of £1069. At Weston-super-Mare there is a convalescent home in connexion with the hospital, and on it there is still a heavy liability.

FOOTBALL CASUALTIES.—On the 14th inst. a member of the Swansea team succumbed to injuries sustained to the spine during a match between the Swansea and Newport teams on the 23rd ult.—The following accidents occurred on Saturday last. While playing a match between the Leeds and Altofts Clubs at Altofts a member of the Leeds team fractured one of his legs and was removed to the infirmary.—At Sandhurst a half-back who was playing for the Lennor team against the Royal Military College fractured his clavicle.—A youth, aged eighteen years, while playing for the Craigpark Club, at Kenny Hill, Glasgow, "became ill," and was carried to a surgeon's, "but was found to be dead from over-exertion."—A young man, aged twenty-one years, of the Leith Athletic Club, fractured his left leg during a League match in Glasgow, and a player in a match, also in Glasgow, fractured his leg.

MR. PETER SWALES, Public Vaccinator, Sheerness, has been awarded the gratuity for successful vaccination for the eleventh time.

THE annual dinner of the Medical Society of London was held in the Whitehall Rooms of the Hôtel Métropole on March 8th, the President, Sir William Dalby, being in the chair. The evening passed most pleasantly, and some excellent singing by Dr. Frederick Roberts, Dr. Samuel West, and others enlivened the proceedings.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—The annual meeting of governors and subscribers was held at the hospital on March 12th, Lieutenant-Colonel Thorneycroft presiding. The state of the finances caused some anxiety, as there was an indebtedness amounting to £2694. The chairman expressed his satisfaction at the providing of wards for the treatment of diseases peculiar to women; a mortuary has also been constructed, the necessity for it having long been felt.

THE DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—A meeting of this society was held on March 14th, 1895, Dr. Pye-Smith, F.R.S., President, being in the chair. Mr. George Pernet read the notes of a case of Acute Fatal Pemphigus. Dr. Stowers read for Dr. Waldo of Clifton notes of a case of Acute Nephritis with Uræmia, attended by an Erythematous Rash and Extensive Desquamation. The following cases were exhibited by Mr. Shield: a Female Patient with Chancre on Right Cheek; Dr. Payne, Erythema Induratum Scrofulosorum (or Bazin's Disease); Dr. Abraham, Bazin's Disease, Adenoma of Alæ Nasi, Pustular Prurigo, Lupus Erythematosus; Dr. Eddowes, Folliculitis Decalvans, Alopecia of Scalp, Lichen Ruber Planus; Dr. Stowers, Lupus Vulgaris, on buttock, Lupus Erythematosus with result of treatment. The President, Mr. Buxton Shillitoe, Mr. Hutchinson, and Dr. Radcliffe Crocker took part in the discussions which followed.

LONDON AND DISTRICT POOR-LAW OFFICERS' ASSOCIATION.—The third annual dinner of this association will be held at the Holborn Restaurant (King's Hall) on Friday, April 5th, 1895, at 6.30 P.M. Mr. Walter H. Long, M.P., late Parliamentary Secretary to the Local Government Board, has kindly agreed to take the chair, and he will be supported by Members of both Houses of Parliament and several distinguished visitors. Mr. Long having brought in the Superannuation Bill and obtained an early date for the second reading, it is hoped that a large number of officers and friends will attend on this occasion, so as to make the dinner a record one, and the committee, relying on such support, have taken the newly opened King's Hall for the occasion. The hon. secs. to the dinner committee, to whom all communications should be made, are Mr. Francis H. Birch (Holborn Union, E.C.) and Mr. Morton F. Cadman. We are requested to state that evening dress will be optional.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The alleged Increase of Insanity.

MR. KENNY has given notice that on an early day he will call attention to the progressive increase in the numbers of the registered insane in all countries, and move "That steps be taken towards the appointment of an International Commission to inquire into the subject from an etiological standpoint, and to consider if any and what measures can be taken to arrest the spread of the disease, especially through hereditary transmission and intemperance, admittedly the two principal factors in the causation of insanity."

Habitual Drunkards.

The Manchester and Salford Social Questions Union has presented to Parliament a petition "for legislation for registration of convicted habitual drunkards, and for restraining owners of licensed premises from harbouring or serving such habitual drunkards."

Baths and Washhouses for the City of London.

MR. A. C. MORTON has had the good fortune to get through all its stages in the House of Commons the Bill to enable the Commissioners of Sewers of the City of London to provide baths and washhouses within the City boundaries. The Bill empowers the Commissioners by a resolution passed at a special meeting to apply the Baths and Washhouses Acts, 1846 to 1882, and to do so without the sanction or approval of

any vestry or other body whose sanction or approval is made necessary by these Acts. It is, however, provided that no bylaw made by the Commissioners in this connexion shall have legal force until approved by the Local Government Board, and, further, an appeal to the sessions is given to any person aggrieved by any bylaw, or order, or direction, or appointment of the Commissioners.

Proposed Amendment of the Public Health Acts.

A Bill, introduced into the House of Commons by Sir Albert Rollit, seeks to amend the Public Health Acts with respect to sewers. It gives local authorities power to recover any expenses incurred by them in cleansing, maintaining, repairing, or replacing private sewers from the owner of the premises for the drainage of which the sewers are used. If there is more than one owner involved, then the apportionment of the expenses is to be made by the surveyor of the local authority or, in case of dispute, by a court of summary jurisdiction. An important clause in the Bill gives the local authority power to enter premises without notice in case of emergency, and do what is necessary in the interests of public health.

The Relief of Distress in Ireland.

The Bill of the Government to make temporary provision for the relief of distress in Ireland provides that at any time before Sept. 1st next the Local Government Board for Ireland may, if they think fit, authorise the board of guardians of any Poor-law union to administer relief in food or fuel, out of the workhouse, for any time not exceeding two months to any poor persons resident in the union. It also indemnifies any boards of guardians who may have done this already with the sanction of the Local Government Board, and declares that no electoral disability shall be incurred by any person receiving this special out-door relief.

HOUSE OF COMMONS.

THURSDAY, MARCH 14TH.

The Employment of Children.

MR. SHAW-LEFEVRE, replying to a question put by Sir John Gorst, said that his attention had not been called to the fact that any children in the Poor-law schools had been put to labour before the age of eleven years. There was, he believed, some evidence to that effect before the committee on these schools, but it appeared that in such cases the industrial work to which the children were put was of a domestic character and very different from work in factories. He proposed, however, to issue an order prohibiting the employment of children below the age of eleven as half-timers.

The Sanitation of Windsor Barracks.

MR. CAMPBELL-BANNERMAN, in answer to Mr. Hanbury, said that a full report was made half yearly with regard to the condition of the cavalry barracks at Windsor. The last report was dated Nov. 12th, but reports upon particular items of sanitation were constantly being made. The drainage of the barracks was not satisfactory, but a complete new system was in hand. Such of the work as could be done while the troops were in occupation was being pushed forward, and the remainder would be executed later in the season, when the barracks would be vacated for the purpose.

Pleuro-pneumonia in London.

MR. HERBERT GARDNER, President of the Board of Agriculture, in reply to Sir Albert Rollit, said he was sorry to have to admit that pleuro-pneumonia was discovered a few days ago in the carcase of a cow brought from a cowshed in Spitalfields. The usual inquiries had been made, and the contact animals slaughtered, but no further cases of disease had been found.

The Indian Cantonments Question.

In the course of a debate on the Army, Sir Richard Temple, who has held high office in India, made a strong speech on this subject. He condemned the new cantonment regulations, saying that they had resulted in an enormous increase in disease. The return of Sir George White, he said, mentioned one-third, but he was afraid that one-half of the men were suffering from disease, which might easily have been made preventable, and which was effectually prevented until the House interfered from a false sense of morality. If war broke out in India it might be necessary to send out a whole fresh army corps to repair the ravages caused by the disease. Morality had benefited not at all. India was placed under heavy additional charges in deference to Lord Roberts and other authorities, and yet all that was entirely nullified by having 30,000 or 40,000 men diseased, owing to the new regulations. Every military officer in India was dead against these regulations, which had also received the protests of the Council and others. They should not be doing their duty to their fellow-subjects in India if they hesitated to speak out. Their speaking out might possibly give offence to some, but they acted under a grievous misapprehension. They had been the means of inflicting great evils on their fellow-countrymen—evils which would last not for a year or two, but probably for a lifetime.

FRIDAY, MARCH 15TH.

The State of the Army.

MR. CAMPBELL-BANNERMAN, Secretary of State for War, speaking on the first of the Army Estimates, gave the House an account of the work of his department during the past year and the state of the army. He reported most satisfactory progress in the vital matter of recruiting. They still, he said, filled up their numbers with growing lads below the standard, but they found that a large proportion of these—about two-thirds—had in a few months of steady life, drill, and good feeding reached the standard. The record of the army in 1894 in the matter of health was good. The admissions to hospital among the home troops were considerably below those of the previous year, and the

death-rate was only 359 per 1000. In connexion with the mobilisation work Mr. Campbell-Bannerman said that five bearer companies and five field hospitals were mobilised at Aldershot and the Curragh, associated with the other arms of the service in the important duties which would devolve upon them in war. These manoeuvres were most instructive to the staff and the other officers, as well as to the department from which they were primarily undertaken. They hoped to repeat these exercises, perhaps on a smaller scale, yearly, in order that the bulk of the Medical Staff Corps now serving might be trained in the work.

MONDAY, MARCH 18TH.

The Reformatory Ship "Clarence."

Mr. Asquith, in reply to Sir George Baden-Powell, said that the conclusions come to after the inquiry into the condition of the reformatory ship *Clarence* were substantially that there was a failure on the part of the committee to visit the ship with sufficient frequency and regularity; and that with regard to the outbreak of small-pox which occurred in November last the Secretary of State was of opinion that no blame was attached to the captain for insufficient precautions having been taken, but after carefully considering the report and the evidence he thought the responsibility must rest with the medical officer, and he had expressed to the committee his opinion that they should reinstate the captain in command of the *Clarence*, and he trusted that steps would be taken by the committee in future to prevent the recurrence of the condition of things which had necessitated the recent inquiry.

Colour-blindness among Railway Servants.

Mr. Bryce informed Sir John Leng that railway companies were not legally compellable to subject their servants to eyesight tests for colour-blindness. The subject, however, was of great interest and importance to the companies and the travelling public, whose interests obviously required that adequate tests for colour-vision should be applied.

The Epidemic on board the "Britannia."

On this subject Mr. E. Robertson, answering a question put by Sir Henry Howorth, said that the sanitary condition of the *Britannia* was at present considered excellent. Frequent inspections of the ship and cadets had been made and every precaution taken to ensure as perfect a hygienic condition as possible. The origin of the late epidemic was distinctly traceable to a cadet who had been exposed to infection previously to joining the ship. Three deaths occurred, one in the person of a colonial cadet from Jamaica, who was undoubtedly affected by the late severe weather; another had been the subject of heart disease, and the third succumbed to severe acute bronchitis. The epidemic might now be regarded as practically at an end.

TUESDAY, MARCH 19TH.

Kitchen Boiler Explosions.

Mr. Bryce, replying to Mr. Weir, said that the principal causes of these accidents were well known, and he was at present considering whether some means might not be adopted of warning householders as winter approached of the measures to be adopted to prevent explosions.

The Opium Commission.

When the House was in Committee of Supply discussing a vote for the expenses of temporary Commissions, Sir E. Ashmead-Bartlett raised the question of the Opium Commission. He was glad, he said, that the expenses of the Commission would be borne by this country, because the people of India did not want the inquiry, which was not in their interest. The result, he believed, would show the absurdity of the anti-opium agitation, and would prove that the use of opium in India, far from being injurious, was in the great majority of cases beneficial to the people who used it. Mr. Cohen said the Commission would be useful if it dispelled the ideas entertained on this subject by many sincere but misinformed and deluded persons.—Mr. Cairne said he did not object to those with whom he was associated being called nababists, but as a matter of fact they did not want the Commission, and voted against the Government on the subject.—Sir John Lubbock explained that the report of the Commission had been sent to India for the signature of some of the members, and would be presented to Parliament as soon as it was returned.

IN COMMITTEE.

Food Products Adulteration.

The Select Committee of the House of Commons on this subject resumed their inquiry on Tuesday, March 19th, under the presidency of Sir Walter Foster.

The only witness they examined at this sitting was Mr. J. C. Lovell, member of a firm of butter importers in London and Manchester, who came forward in his individual capacity and as representing the Provision Trade Section of the London Chamber of Commerce and the London Butter Association. Speaking with wide and long experience he said that a great amount of butter adulteration prevailed. In the case of his own firm they had found it necessary to take steps to protect themselves from large quantities of adulterated butter coming from France. They succeeded in getting numerous prosecutions in that country, and in this way put down the adulteration to a very large extent. Lately there had been an association of the London butter merchants formed for the purpose of taking up this question. He did not in the least object to margarine. On the contrary, he regarded it as a most necessary and good article of food, and he would not interfere in any way whatever with its honest sale; but he did object to butter mixtures, of which enormous quantities were made and sold. He was of opinion that it should be an offence against the law to ally butter and margarine in a mixture. It was this mixing of butter and margarine that opened the door to fraud and injured the butter trade. He was aware that under the Margarine Act any mixture that contained margarine must be described as margarine, but the law was not respected. Many men who sold margarine cared nothing for the penalties under the Act, and when they were imposed upon them did

not alter the course of their trade in any way. He suggested that the fines should be much heavier, and that for the third offence imprisonment should be inflicted. He also suggested that the manufacturer of margarine and margarine mixtures and the wholesale merchant and retailer should be licensed, his licence to be exhibited on his premises. In London there were many persons who were known to buy margarine, and who did not sell it—that was to say, did not sell anything by the name of margarine. He considered it would be unjust and unreasonable to impose any restriction upon the colouring of butter, because in certain districts and at certain seasons it was absolutely necessary to colour it. Most of the evils he complained of would long ago have disappeared had the existing law been vigorously carried out. For example, the Margarine Act gave the Customs authorities power to take samples of goods in transit, and they had never done so except upon information given them by persons in the trade. Now, in his opinion there should be systematic examination at the port of entry. Then there was the neglect and carelessness of the local authorities and their inspectors. In some places one was inclined to say that the inspector winked at offences, and in others it was no doubt true that the inspector worked under great difficulties. For instance, the people knew him at once by his uniform, and when he went into a shop and asked for butter he must certainly get it, although ordinary customers might not find themselves so fortunate. His suggestion was to have travelling inspectors who were not known in the districts. He strongly objected to margarine or mixtures being packed as they were now, in known butter packages. The manifest object of the present system was to assist the retailer in selling the margarine or mixture as pure butter. He found that every known package for the carriage of butter had been imitated by people dealing in margarine or mixtures. In this connexion he suggested that these articles could very well be confined, as was the case in Denmark, to one package. The London Butter Association had only been at work for a month, but the mere fact of its establishment had done good. The association employed inspectors who were told to go anywhere they liked to detect fraud, and already there had been a number of convictions. Within the last two years a system had sprung up of retailers mixing butter and margarine on their own premises by the use of machines specially made for the purpose. It was difficult to detect fraud here, because the quantities made were very small. As to the water to be allowed by law in butter, he thought 17 per cent. would be a perfectly safe maximum.

The Committee then adjourned.

The Committee met again on Wednesday, March 20th, with Sir Walter Foster in the chair.

Mr. R. H. Slater, shipper of butter from Rennes in Brittany, said he had come to the conclusion that the facility with which the adulteration of butter in France was carried on arose from the admitted incompetence of French analysts to detect a percentage of margarine of less than 10 per cent. French shippers, taking advantage of this, were careful to put in at least 10 per cent. of margarine, secure, as they were, against detection. There was a law in France to prevent the mixing of butter and margarine, but it was of no practical advantage. They had also a law prohibiting the sale of margarine as butter, and requiring the exhibition of the words "margarine," "oleomargarine," or "grease" where these substances were used, but this law could be evaded in a number of ways. He himself, in his own business, had been invited to buy margarine which the sellers assured him could not be detected in Brittany butter in a less proportion than 15 per cent., and he knew very well that large quantities of margarine were received in France by shippers of butter. There was so strong a feeling about the injuriousness of this competition among honest butter shippers in France that they had declared to the Government that unless it was prepared to help them with efficacious legislation, they would be obliged to imitate their less scrupulous competitors, or see themselves ruined. "The French Government," he might say, "had taken steps to prevent the use of margarine in hospitals and public institutions, on the ground that it was injurious to health." What he recommended was that the English Government should approach the French Government, and bring such pressure to bear as would make it decide to pass stringent laws against the margainers, and see that they were applied all round. He thought there should be a regular system of analysis at the ports of entry for butter, or reputed butter, coming from such countries as Holland and Belgium, and the heavier fines should be inflicted upon offenders.

Cross examined by Mr. Whiteley, witness expressed the individual opinion that margarine was injurious to health.

By the Chairman.—In his view the reason why the French Government did not interfere was that the houses who dealt in margarine were very powerful, and not that their interference would involve dearer butter and butter substitutes for the people of France. At the present moment in the towns of France the people paid very much more for French butter than did the people of England for the same butter.

Mr. J. T. Horner, who represented the Dairy Trade and Can Protection Society, gave evidence as to the analysis of milk. He told how out of 2229 samples, no fewer than 724 were found to fall short of a standard of 12 per cent. total solids, and he strongly advocated the adoption of a low standard to meet the varying condition and quality of cows. If the constituent parts were fixed they should not be more than 8.50 per cent. and 2.50 per cent. At present there was no legal standard, and in prosecutions they had to depend largely upon the particular idiosyncrasy of the analyst.

The Chairman read to the Committee a memorial which had been received from the London Butter Association, presenting the views of that body. The substance of the memorial will be found in the report of the evidence given by Mr. Lovell.

Mr. Kilbride, one of the members of the Committee, made complaint that in certain prosecutions in England for watering butter use was being made of inaccurate statements of evidence given before this Committee.

The Chairman said that the Committee could do nothing to prevent this, but reminded the hon. member that it was open to any one to procure the Blue-book containing the true record of the evidence taken.

The Committee then adjourned until Tuesday, March 26th.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

ALLEN, JOSHUA, M.R.C.S., has been reappointed Medical Officer of Health for the Belper No. 1 Sanitary District.

BEATTIE, R., M.D., M.Ch. Irel., M.R.C.S., has been appointed Honorary Medical Officer to the Dewsbury and District General Infirmary.

BREW, R. W., M.B., B.Ch., B.A.C. Dubl., has been appointed Medical Officer for the Bunickerry Dispensary District.

CALVERLEY, J. E. G., L.R.C.P. Lond., M.R.C.S., has been appointed Assistant House Physician to the Metropolitan Hospital.

COOMES, GEO. NOBLE, L.R.C.P. and S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer to the Government of His Highness the Maharajah of Cochin, South India.

COSLYFFE, T. V., M.R.C.S., L.R.C.P., has been appointed House Surgeon to the Manchester Royal Infirmary.

DOCKRAY, H. S., B.Sc. Lond., M.R.C.S., L.R.C.P., has been appointed House Surgeon to the Manchester Royal Infirmary.

DUN, H. W., M.B., M.S. Edin., has been appointed Resident Assistant Medical Officer and Dispenser at the Workhouse, Sheffield Union.

FLEGG, F. A. MARTIN, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A., has been appointed House Surgeon to the Seamen's Infirmary and General Hospital, Rangoon, and Visiting Surgeon to the Hantsgate and St. Lawrence Royal Dispensary.

FLEET, T. B., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed House Physician to the Manchester Royal Infirmary.

GAYLOR, EDWARD, L.R.C.P. Edin., L.F.P.S. Glasg., L.M., has been reappointed Medical Officer of Health for the Belper Rural Sanitary District.

HAMILTON, J. C., M.B. Dubl., L.R.C.S., L.M. Irel., has been appointed Medical Officer for the Rathdown Union Workhouse.

BOARE, WILLIAM WALLIS, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Chief Medical Officer to the Hospitals and Estates of the New London Borneo Tobacco Company, Limited, British North Borneo.

ROBERTS, R. T., M.R.C.S. Eng., L.R.C.P., has been appointed House Surgeon to the Mauchette Royal Infirmary.

HUGH, J. H., L.R.C.P., M.R.C.S., has been appointed Assistant Medical Officer to the East Dulwich Infirmary.

JON, H. PERCY, L.R.C.P. Lond., M.R.C.S., has been appointed Honorary Medical Officer to the Newark Town and District Hospital, vice Matterson.

LAWRENCE, A. E. ARST., M.D., has been reappointed Physician Accoucheur to the Bristol General Hospital for a third period of ten years.

LOVE, F. J., F.C.S., F.I.C., has been reappointed a District Agricultural Analyst for the County of Wiltshire, under the Fertilisers and Feeding Stuffs Act, 1893.

MACINTOSH, ANGUS, M.D., L.F.P.S. Glasg., &c., has been reappointed Medical Officer of Health to the Chesterfield Rural District Council, and also to the Urban District Councils of Clay Cross and Dronfield.

MELLAND, C. H., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed House Physician to the Manchester Royal Infirmary.

MCDUGALL, P., B.Sc. Lond., M.B., Ch.B. Vict., has been appointed House Surgeon to the Manchester Royal Infirmary.

KEV, THOMAS WM., F.R.C.S. Eng., Consulting Surgeon to the Middlesex Hospital, has been appointed Consulting Surgeon to the London Skin Hospital, 40, Fitzroy-square, W.

PITFORD, HERBERT, M.A., M.B., C.M. Cantab., has been appointed Third Assistant Medical Officer at the Worcester County and City Lunatic Asylum.

RICHARDSON, W. J., M.D., M.Ch. Irel., B.A.C., has been appointed Honorary Medical Officer to the Dewsbury and District General Infirmary.

SHARPE, W. C., M.B. Edin., has been appointed Senior Physician to Smedley's Hydropathic Institution, Matlock.

SEBRITT, E. MARKHAM, M.D. Lond., F.R.C.P., has been reappointed Physician to the Bristol General Hospital for a third period of ten years.

STEWART, BOTHAM C., M.R.C.S., L.S.A., has been appointed Medical Superintendent to the Leicestershire and Rutland Asylum, vice W. H. Higgins, M.B., resigned.

THOMPSON, ROBERT, M.D., B.S., has been appointed Honorary Ophthalmic Surgeon to the Ipswich Hospital, Queensland, and also Visiting Ophthalmic Surgeon to the Blind Institution, Brisbane, Queensland.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BARSTAPLE UNION.—Medical Officer to the Sick Poor within the parishes of Ilfracombe, Morchoe, Bittadon, and West Down. Salary £70 a year, upon certain conditions, but midwifery fees allowed. Applications to the Clerk, Barnstaple.

BETHLEHEM HOSPITAL.—Two Resident Clinical Assistants. Applications to the Clerk, Brideswell Hospital, New Bridge-street, E.C.

BLOOMSBURY DISPENSARY.—Physician. An honorarium of £105 is annually voted to the physician. Applications to Mr. C. E. Baker, 12, Bloomsbury-street, W.C.

BOLTON INFIRMARY AND DISPENSARY.—Junior House Surgeon for twelve months. Salary £80 per annum, with furnished apartments, board and attendance.

BRADFORD INFIRMARY AND DISPENSARY.—House Surgeon, unmarried. Salary £110 per annum, with board and residence.

BRIGHTON THROAT AND EAR HOSPITAL, 23, Queen's-road, Brighton.—Non-Resident House Surgeon. Salary at the rate of £52 per annum.

CAMBERWELL HOUSE, 33, Peckham-road, Camberwell.—Assistant Medical Officer, unmarried. Salary to begin at £100 a year, with board, lodging, and washing.

CHARING-CROSS HOSPITAL, London.—Assistant Physician.

CLAYTON HOSPITAL AND WAKEFIELD GENERAL DISPENSARY, Wakefield.—Junior House Surgeon, unmarried. Honorarium £40 per annum, with board, lodging, and washing.

CITY ORTHOPAEDIC HOSPITAL, Hatton-garden, E.C.—Honorary Assistant Surgeon.

COUNTY ASYLUM, Rainhill, near Liverpool.—Assistant Medical Officer, unmarried. Salary to commence at £100 a year, with prospect of an annual rise of £25 up to £200, and further increase according to promotion, together with furnished apartments, board, attendance, and washing.

EAST LONDON HOSPITAL FOR CHILDREN, Glamies-road, Shadwell, E.—House Physician. Board, lodging, &c. provided.

GLANMORGAN COUNTY ASYLUM, Bridgend.—Junior Assistant Medical Officer; single. Salary £100 a year, with board (no beer or wine), lodging, washing, and attendance.

HOLBORN UNION.—Medical Officer of the Union Schools at Mitcham, Surrey. Salary £100 per annum, non-resident. Applications to the Clerk to the Guardians, Holborn Guardians' Office, Clerkenwell-road, E.C.

HOSPITAL FOR WOMEN, THE (THE LONDON SCHOOL OF GYNECOLOGY), Soho-square, W.—Clinical Assistants.

LEEDS UNION.—Assistant Medical Officer for the Workhouse, Schools, and Infirmary, situated in Beckett-street, Leeds. Salary £100 per annum, with board, washing, apartments, and attendance. Applications to the Clerk, Union Offices, East-parade, Leeds.

LEICESTERSHIRE AND RUTLAND ASYLUM.—Assistant Medical Officer, unmarried. Salary £150, increasing £10 yearly to £200, with board, lodging, and washing. Applications to the Clerk to the Visitors, 10, New-street, Leicester.

LINCOLN COUNTY HOSPITAL, Lincoln.—House Surgeon, unmarried. Salary £100 per annum, with board, lodging, and washing.

LONDON HOSPITAL, Whitechapel, E.—Surgical Registrarship. Salary £100 per annum.

LONDON HOSPITAL MEDICAL COLLEGE, THE, Mile End, E.—Assistant Demonstrator of Anatomy. Salary £30 per annum.

MILLER HOSPITAL AND ROYAL KENT DISPENSARY, Greenwich-road, S.E.—Junior Resident Medical Officer, for six months. Salary at the rate of £50 per annum, with board, attendance, and washing.

NORFOLK COUNTY ASYLUM, Thorpe, Norwich.—Junior Assistant Medical Officer. Salary £110 per annum, increasing £10 annually to £150, with board, lodging, and washing.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, Shoreditch, N.E.—Physician. Applications to the Secretary, Office, 27, Clement's-lane, E.C.

ROYAL COLLEGE OF PHYSICIANS, London.—Milroy Lecturer.

SURREY COUNTY LUNATIC ASYLUM, Brookwood, near Woking.—Second Assistant Medical Officer. Salary £120, with board, lodging, attendance, and laundry, but not beer. Applications to the Medical Superintendent.

TAMTON AND SOMERSET HOSPITAL, Tamton.—House Surgeon for three years. Salary £100 per annum, with board, lodging, and washing in the Hospital. Also Honorary Physician.

WEST RIDING ASYLUM, Menston, near Leeds.—Third Assistant Medical Officer. Salary to commence at £130 a year, rising £10 annually to £160, with board and apartments.

YORKSHIRE COLLEGE, Leeds.—Demonstrator of Anatomy. Applications to the Registrar.

Births, Marriages, and Deaths.

BIRTHS.

CANE.—On March 13th, at Peterborough, the wife of Dr. Leonard Cane, of a daughter.

DAVIES.—On March 17th, at Oakland-terrace, Cricklewood, N.W., the wife of Dr. H. O. Davies, of a son.

EDGE.—On March 15th, at Maidenhead, the wife of A. J. Edge, M.B. Lond., of a son.

STOCKER.—On March 12th, at Weedon, Northamptonshire, the wife of E. Gaved Stocker, M.R.C.S., of a son.

MARRIAGES.

DENT—PARK.—On March 14th, at St. Barnabas', Kensington, Herbert Crowley Dent, of Cromer, Surgeon-Captain A.M.S. (retired), to May Burton, youngest daughter of the late Rev. John Park, formerly Vicar of Ramsgate, Lancashire.

SETON—ARMSTRONG.—On March 16th, at St. Simon's, Southsea, Surgeon-Captain Bruce Gordon Seton, I.M.S., eldest son of the late Lieutenant-Colonel A. R. Seton, R.E., to Elma, daughter of Lieutenant-Colonel F. H. Armstrong, Southsea.

DEATHS.

BALL.—On March 17th, at Cliff House, Stoke-upon-Trent, Daniel Ball, F.R.C.S., in his 96th year.

BANKS.—On March 11th, at Brooke House, Riseley, Bedford, Philip Humbley Banks, M.R.C.S., L.A.C., aged 62.

CHILD.—On March 15th, at Silverhowe, College-park, Willesden, Warwick Long Child, M.D., M.R.C.S., in his 39th year.

COATES.—On March 15th, at Summer Villa, Hythe, Kent, Surgeon-Major John Coates, M.D., late 24th Regiment, in his 69th year.

CUNLIFFE.—On March 12th, at St. Heliers, Jersey, William Shirabole Cunliffe, M.R.C.S., in his 53rd year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (1 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynecological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopaedic (2 P.M.), City Orthopaedic (4 P.M.).

TUESDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1.30 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Gt. Northern Central (2.30 P.M.).

WEDNESDAY.—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), National Orthopaedic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.).

THURSDAY.—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (2 P.M.), Soho-square (2 P.M.), North West London (2 P.M.).

FRIDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.).

SATURDAY.—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY.—MEDICAL SOCIETY OF LONDON.—8.30 P.M. Mr. Bland Sutton: On a case of Tubal Pregnancy and one simulating Tubal Pregnancy.—Mr. L. A. Bidwell: An Operation for Extra-uterine Gestation involving Resection of Intestine.

TUESDAY.—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—Dr. James Taylor: On Nervous Symptoms and Morbid Changes in the Spinal Cord in certain cases of Profound Anemia (with lantern illustration).

WEDNESDAY.—HENTERTIAN SOCIETY (London Institution).—8.30 P.M. Dr. Fortescue Fox: The Varieties of Rheumatoid Arthritis.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY.—LONDON POST-GRADUATE COURSE.—Royal London Ophthalmic Hospital, Moorfields, 1 P.M., Mr. A. S. Morton: Ocular Injuries.—London Throat Hospital, Gt. Portland-st., W., 8 P.M., Dr. Law: Demonstration of Cases.

ROYAL COLLEGE OF SURGEONS.—5 P.M. Professor Joseph Griffiths: Observations on the Testis.

SOCIETY OF ARTS.—8 P.M. Dr. D. Morris: Commercial Fibres.

TUESDAY.—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 2 P.M., Dr. Craig: Impulsive, Homicidal, and Moral Insanity.

ROYAL INSTITUTION.—3 P.M. Prof. Charles Stewart: The Internal Framework of Plants and Animals (XI.).

THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—3 P.M. Subject of Lecture: Fire.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL.—4.30 P.M. Dr. Dundas Grant: Diagnosis and Treatment of Diseases characterised by Visible Changes in the Organs of Hearing.

ROYAL COLLEGE OF PHYSICIANS, LONDON.—5 P.M. Dr. H. D. Rolleston: Suprarenal Capsules. (Third Goulstonian Lecture.)

WEDNESDAY.—WEST LONDON HOSPITAL (Hammersmith, W.).—5 P.M. Dr. Ball: Throat Cases. (Post-graduate Course.)

ROYAL COLLEGE OF SURGEONS.—5 P.M. Professor Joseph Griffiths: Observations on the Testis.

LONDON POST-GRADUATE COURSE.—Royal London Ophthalmic Hospital, Moorfields, 8 P.M., Mr. W. Lang: Squint.—Hospital for Skin Diseases, Blackfriars, 1 P.M., Dr. Payne: Ringworm and Vegetable Parasitic Diseases.

SOCIETY OF ARTS.—8 P.M. Mr. Horace Wilmer: Modern Photogravure Methods.

THURSDAY.—ROYAL INSTITUTION.—3 P.M. Mr. E. B. Taylor: Animism, as shown in the Religions of the Lower Races (I.).

LONDON POST-GRADUATE COURSE.—Hospital for Sick Children, Gt. Ormond-st., 3.30 P.M., Dr. Penrose: Cases in the Wards.—National Hospital for the Paralyzed, Bloomsbury, 2 P.M., Mr. Victor Horsley: Surgery of the Nervous System.—Central London Sick Asylum, Cleveland-st., W., 5.30 P.M., Mr. John Hopkins: Cases in the Wards.

SOCIETY OF ARTS.—4.30 P.M. Capt. F. E. Younghusband: Chitral and the States of the Hindu Kush.

ROYAL COLLEGE OF PHYSICIANS, LONDON.—5 P.M. Dr. G. Fielding Blandford: The Diagnosis, Prognosis, and Prophylaxis of Insanity. (First Lumleian Lecture.)

LONDON SKIN HOSPITAL.—8 P.M. Mr. Augustus Harbord: Syphilis, Acquired and Congenital.

FRIDAY.—LONDON POST-GRADUATE COURSE.—Bacteriological Laboratory, King's College, 3 to 5 P.M., Prof. Crookshank: Tetanus, Rabies, and Cholera.

THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—3 P.M. Subject of Lecture: Air.

THE CANCER HOSPITAL (FREE) (Fulham-road, Brompton, S.W.).—4 P.M. Mr. E. Cotterell: Cancer of the Oesophagus.

ROYAL COLLEGE OF SURGEONS.—5 P.M. Professor Joseph Griffiths: Observations on the Testis.

ROYAL INSTITUTION.—9 P.M. Prof. H. E. Armstrong: The Structure of the Sugars and their Artificial Production.

SATURDAY.—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 11 A.M., Dr. Percy Smith: Lunacy Law.

ROYAL INSTITUTION.—3 P.M. Lord Rayleigh: Waves and Vibrations (V.).

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

UNDER no circumstances do the Proprietors authorise the insertion of loose advertisement circulars and handbills in THE LANCET. Any such announcements are inserted by the newsagents, whom the Proprietors cannot control. At the same time, the Manager will be glad if readers will send him copies of any circulars, with the name and address of the agent through whom they obtain THE LANCET, and the Manager will then endeavour to mitigate the nuisance.

NEWSPAPER THERAPEUTICS AND THE INFLUENZA EPIDEMIC.

JUMPING into a medical practitioner's carriage and eliciting his views with regard to influenza between one patient's house and another is the last device of that modern representative of the Inquisition, the newspaper interviewer. The victim in this instance was a practitioner who, in spite of his strong anti-alcoholic views, is a man with the quality of sweet reasonableness. But it is to be regretted that he should give material for such scrappy writing on a serious medical subject, especially to a contemporary which is one of the chief mediums of all the facts that harass and hinder scientific medicine in its attempts to get at the roots of disease. Medical men best consult the dignity of their profession and the interest of the public by doing their best in the sick-room and in the study, and leaving to others the interviewer.

Medicus is thanked for his communication.

THE EXAMINATION FOR THE NAVAL MEDICAL SERVICE.

To the Editors of THE LANCET.

SIRS,—Can any reader of THE LANCET inform me as to the best books to read for the Naval Medical Service examination in biology, physical geography, and physics? I shall be much obliged for the information.

March 18th, 1895.

I am, Sirs, yours faithfully,

T. D. L.

BONESSETTING IN THE NORTH OF ENGLAND.

Whether the difference be in the bones or the brains of the people of the north of England, they seem to have a great love for bonesetters. The *Carlisle Journal* in a recent number publishes the full names and addresses of twelve persons alleged during the preceding week to have sustained various specified fractures, dislocations, and bruises, and all of whom were attended by one bonesetter in a small Cumberland town called Aspatria. There seems to be a perfect epidemic—plentiful as influenza cases—of fractured collar-bones, dislocated knees, wrists, ankles, and shoulders. We must, however, perhaps, not take these diagnoses quite so seriously as our lay contemporary.

First Swiss Alpine Milk Exporting Co., Ltd.—It is obviously not correct to say generally that cane sugar &c. are very harmful to the body. We quite agree, however, with the remark in the succeeding paragraph relative to the "special objection" to cane sugar in infant feeding.

Mr. H. Percival Gaston.—Such quackery is not to be reached under the Medical Acts. It should be dealt with by the police authorities as contrary to public morals.

A MIDWIFE CENSURED.

At the Chelsea town hall an inquiry was lately held into the death of an infant one week old, the illegitimate child of Thomas Rowles and Florence Jones of Chelsea. A midwife, Mrs. Harwood, attended, and said the child was feeble and not at full time. The coroner thought the evidence very unsatisfactory, and showed neglect on the midwife's part in not calling the attention of the medical practitioner to the child's condition. Dr. Campbell had visited the house, but was not informed of the weakly state of the child. The jury added to their verdict of "Death from syncope following premature birth" that the nurse acted without due care in failing to call the attention of the medical practitioner to the condition of the child.

Mr. D. H. Willey.—We never recommend individual practitioners. The regular medical attendant can advise upon the necessity of a consultation and upon the proper person to be consulted.

IS PARALYSIS AFTER A SORE-THROAT A PROOF THAT THE DISEASE WAS DIPHTHERIA?

To the Editors of THE LANCET.

Sirs,—It is asserted that if any doubt exists about the nature of a sore-throat the subsequent development of paralysis is proof that the disease the patient suffered from was diphtheria. I must traverse this statement, for I lately attended a case in an adult, and I diagnosed pseudo-diphtheria (unilateral septic follicular tonsillitis), and soon after recovery the patient developed paralysis of the soft palate, which lasted for about a week. There were three young children in the house at the time, and they were simply excluded from the sick room of their mother, who was the patient, but no other precautions were taken. No one in the house and no visitor took the disease. There was no marked depression of the system and no albuminuria. It is interesting to remember that women after childbirth suffer sometimes from polyneuritis, and that this form of paralysis has a septic origin.

I am, Sirs, yours faithfully,

HENRY ALSTON,

Trinidad Government Service.

Trinidad, Feb. 21st, 1895.

THE CASE OF MR. C. B. TOWNSEND.

PREVIOUSLY ACKNOWLEDGED.

Further subscriptions are earnestly desired to put the family in the way of self-support, which will require about £200. The Rev. H. Townsend, 41, King Henry's-road, N.W., will receive subscriptions.

A BISHOP AND QUACK TESTIMONIALS.

We lately commented on the unseemliness of a clergyman, who has in the cure of souls a sufficient care, undertaking the heavy responsibility of recommending cures for the body. We have to-day to complain of something still more unseemly—viz., of a bishop (the Right Reverend the Bishop of Swansea) recommending a quack medicine—Mortimer's Croup-cough and Whooping-cough Mixture. Surely, the Bishop has not considered the matter and the risks of such diseases. We are unwilling to criticise so great an ecclesiastical authority; but we beg him to remember that his authority does not extend to medicine, and that by writing as if it did he damages the respect of reasonable men for the use of his authority even in his own sphere.

DEGRADATION OF MEDICAL SERVICE AT IPSWICH.

We refer in another column to the wide tendency to degrade medical service by abuses of the club system. The following handbill is an illustration of our meaning:—

"THE PEOPLE'S MEDICAL AID SOCIETY, IPSWICH.

"The above Society is now being formed for the purpose of securing for its members sound medical advice, attendance, and a supply of medicine whenever they are in need of same. A weekly subscription of one penny for adults, and one half-penny for children will be charged. No entrance fees. Members will be entitled to immediate benefit providing they are in a good state of health at the time of entry.

"It is hoped that sufficient members will be enrolled so as to enable the Society to have the exclusive services of its Medical Officer. All persons interested in the Society are kindly requested to make it known amongst their friends. Further particulars may be obtained from the Secretary, W. H. Baldwin, 25, St. Peter's Street, Ipswich."

We do not see the name of Mr. W. H. Baldwin in the Medical Register. We must content ourselves now with directing the attention of the profession in Ipswich to this wretched bill, and asking them fully to investigate its nature. Any medical man who lends himself to coöperation with Mr. Baldwin would do much to forfeit the respect of his professional brethren.

Miss Emma H. Fredriewsk.—We do not feel at liberty to give our correspondent the addresses in question without knowing more fully the nature of the responsibility she desires to share with the leaders of the profession.

"SULPHUR v. ANTITOXIN IN THE TREATMENT OF DIPHTHERIA."

To the Editors of THE LANCET.

SIRS,—I have no desire to enter into controversy regarding a remedy such as sulphur and the sulphites, of which I have a high opinion in the treatment of diphtheria; but I desire to acknowledge that Mr. Hawkins Cutlibert is quite correct in saying that there is no allusion to antitoxin having been used as an auxiliary and in combination with other remedies at the North-Western Fever Hospital in the report published in THE LANCET of Feb. 2nd. I was, indeed, surprised to notice this omission, since I was well informed that the original return contained a distinct statement to that effect, and I mentioned the circumstance, with an expression of regret at its suppression, in my last lecture on diphtheria, as recorded in the *Medical Press and Circular*, Feb. 13th, p. 160.

I am, Sirs, yours faithfully,

Mansfield-street, W., March 18th, 1895.

LENNOX BROWN.

A REGISTERED MEDICAL PRACTITIONER AND DENTAL ADVERTISING.

The laudation of a dentist by a registered medical practitioner in the way of a testimonial printed in the form of a handbill, based on his observation of cases in which he acted as chloroformist, is a form of double advertisement which may be original, but is certainly entitled to no other praise. The author, Mr. George Gresswell, M.A. Oxford and Cape, possesses the combined qualifications of the Edinburgh Colleges and the Faculty of Glasgow. If he will consult these bodies on the taste of the handbill he will be enlightened.

ERRATUM.—At the end of the third line of Dr. Barron's letter on "The Influenza Epidemic" in our last issue, page 725, the words "in area" should be added after "very similar."

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers

have been received:—*Weekly Budget, Medical Record, Echo, Eastern Morning News, Bury Guardian, Cork Weekly Examiner, Cheltenham Free Press, Birmingham Gazette, Sheffield Telegraph, Sussex Daily News, Newcastle Daily Chronicle, Irish Times, Ashton-under-Lyne Reporter, Norfolk Chronicle, Carlisle Express, Civil Service Gazette, Dunelm Weekly News, Leicester Post, Chorley Guardian, Liverpool Mercury, Manchester Guardian, Derbyshire Times, Wolverhampton Chronicle, Western Morning News, Justice, Electrical Review (New York), City Press, Grimsby News, Western Gazette, Northern Whip, Horncastle News, Stockton Herald, Craven Herald, Leeds Mercury, Sanitary Record, Architect, Bristol Mercury, Morning, Mining Journal, Liverpool Daily Post, Reading Mercury, Yorkshire Post, Builder, Times of India, West Middlesex Standard, Pioneer Mail, Weekly Free Press and Aberdeen Herald, Hertfordshire Mercury, Local Government Chronicle, The Welshman, Surrey Advertiser, St. Bartholomew's Hospital Journal, West Middlesex Advertiser, Local Government Journal, Invergordon Times, Health, Cycle, Southampton Echo, Ilfracombe Chronicle, Evening Echo, Dublin, Long Eaton Pioneer, Kettering Guardian, &c., &c.*

Communications, Letters &c. have been received from—

Terms for Position Pages and Serial Insertions on application.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to fictitious names or initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials &c. sent to the Office in reply to advertisements; copies only should be forwarded.

Terms for Serial Insertions may be obtained of the Manager, to whom all letters relating to Advertisements or Subscriptions should be addressed. THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 2, Rue Traversière, Amières, Paris.

Three Lectures

UPON THE TESTES.

Delivered before the Royal College of Surgeons of England on
March 25th, 27th, and 29th, 1895,

By JOSEPH GRIFFITHS, M.A. CANTAB.,
M.D. EDIN., F.R.C.S. ENG.,

ASSISTANT TO THE PROFESSOR OF SURGERY IN THE UNIVERSITY OF
CAMBRIDGE; HUNTERIAN PROFESSOR OF SURGERY AND PATHOLOGY
AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND; ASSISTANT
SURGEON TO ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

LECTURE I.

Delivered on March 25th.

MR. VICE-PRESIDENT AND GENTLEMEN,—Before commencing these lectures allow me to offer my sincere thanks to the President and Council of the College for electing me to the honourable position of Hunterian Professor of Surgery and Pathology, and to express the hope that I shall be able to justify the confidence they have thus placed in me and to do credit to the office I have the honour to hold. I propose to embody in these lectures the results of my own observations and experiments upon the testis and to give a general review of them rather than to recount all the details which have taken me some years to gather and to put together. By means of such a general review I hope to convey a concise summary of the views I have put forth to some extent in a series of papers already published in the *Journal of Anatomy and Physiology*. For a discussion upon the views of other writers and for a fuller and more detailed account of my own observations I shall often have to refer to one or other of these papers. I shall endeavour to make the subject as interesting as I possibly can, and I hope you will listen to me with indulgence and overlook any shortcomings on my part.

I will, in the first place, give an account of the structure of the testis in early life, in adult life, and in old age, and then proceed to consider the influences this organ exercises upon the growth and development of the sexual glands that are accessory to it, as well as the influence it exerts upon the character of the body and the mind. Secondly, I propose to give an account of the state of the testis, and of the function exercised by it when it is retained at some point in the course of its descent, or transition, from the abdominal cavity to the scrotum. Lastly, I will state the effects upon the testis of obliteration of the vas deferens, whether that be induced by disease or by experiment.

STRUCTURE OF THE TESTIS.

The testis, as is well known, is an organ which attains neither its full size nor its full function until the onset of puberty—a time that varies in different persons and in different climes. With the attainment of the full size and the full function of the testis the features which we regard as characteristic of the male sex are developed.

1. *In the boy.*—The body of the testis of a boy, say at ten years of age, measures about 15 mm. in length by 10 mm. in breadth, and also 10 mm. from before backwards; a transverse section, therefore, is nearly circular. It is firm and of compact structure. The seminal tubules are almost indistinguishable from one another and from the somewhat dense intervening connective tissue. In minute structure the body of the testis consists of numerous tubules closely packed and firmly bound together. These tubules are but little convoluted, and each of them is surrounded by a well-marked tunica propria composed of two or three layers of flattened connective-tissue cells with flattened and elongated nuclei. The intertubular connective tissue, which is of a fibro-cellular nature, is relatively large in amount, and in this the bloodvessels, lymphatics, and nerves run. Each tubule is composed of a solid column or rod of cells, the cells at the periphery of the tubule being of a cubical shape, and those filling the centre polygonal or irregular in outline. There is at this stage in the development of the seminal tubules no lumen, and all the cells seem to be in a quiescent state. In the corpus Highmori, which is small, the rete testis is simple, and the few channels seen in it are lined by a single layer of low cubical cells resting

No. 3735.

directly upon dense fibrous tissue. The epididymis is relatively large to the body of the testis, this being always so in early life, and it is also large in cases of atrophy or want of development of the organ. (See Fig. 1.) In its upper end the tubules

FIG. 1.

Right testis of a boy aged five years. Natural size.

are small and empty, and are lined by a single layer of sub-columnar, non-ciliated cells having between their narrow and attached ends other small, irregular, or pear-shaped cells. The walls of these tubules are chiefly composed of several layers of those flattened or spindle-shaped cells which we are in the habit of recognising as incompletely developed unstriated muscular fibres. The tubules are bound together by cellular connective tissues. (See Fig. 2.) Thus in the child the

FIG. 2.

Section of epididymis of a boy aged ten years. $\times 50$.

globus major of the epididymis differs from the testis in that the lumen of its tubules is not occupied by cells, and that the cells lining them are of the subcolumnar, non-ciliated variety. They differ from those of the adult, as will be seen further on, by the smallness of the cells and the absence of cilia upon them. The lower part of the epididymis is composed of the coiled commencement of the vas deferens, connected together by loose areolar tissue.

2. *In the adult.*—In the adult the body of the testis is large, soft, and plump, measuring on an average $1\frac{1}{2}$ in. in length, $1\frac{1}{4}$ in. in breadth from before backwards, and 1 in. from side to side. It weighs between six and eight drachms. On section through the tunica albuginea the tubules, resembling twisted threads, immediately bulge outwards under pressure of the investing tunica. They are easily separated from one another owing to the intervening intertubular connective tissue being small in amount and very delicate in its structure. There is usually a certain degree of asymmetry between the two organs—the left and right—as, indeed, is the case in other bilateral organs of the body. This asymmetry between the two testicles, though usually very slight—the left being often the larger and more dependent—may be seen in a striking degree in a specimen in the Cambridge Pathological Museum, which shows the testes taken post mortem from a man aged forty-four years. The left, which was the smaller, measured only 30 mm. in length by 20 mm. in breadth; whereas the right measured 50 mm. in length by 35 mm. in breadth. (Fig. 3.) The epididymis was relatively larger to the body of the testis in the left or smaller than in the right. Each organ was

natural in form and in structure, and in each the formation of the spermatozoa was going on at the time of death, as shown by the presence of special sperm cells in the interior of the seminal tubules. [Thus, though both were natural in

with some debris of cells. Thus, at the periphery of each seminal tubule there are, as it were, parent cells; within these there are daughter cells, some of the innermost of which give rise to spermatozoa-forming cells, and others, perhaps all the remainder, break up to form the fluid portion of the secretion.¹ In the epididymis (Fig. 4), which is relatively smaller than in the boy, the tubules of the globus major are fully developed, and have a large lumen filled with the seminal secretion, which contains, during life, active spermatozoa. Each tubule consists of a thick wall of unstriated muscular fibres and is lined by a single layer of tall columnar cells with fine long cilia at their free margins. In the adult, so far as can be judged from their structure, the seminal tubules are more or less constantly producing the seminal secretion, which is made up of spermatozoa derived from some of the daughter cells already mentioned, and of a special secretion formed in all probability from the dissolution of those daughter cells that do not give rise to the formation of the special and most power-giving cells in the animal kingdom—the spermatozoa. Thus, in the testes of the adult the seminal tubules differ from those in the child in the presence of these sperm and secretion producing cells, as well as in the presence of a central lumen; and the tubules of the epididymis (upper end) differ in being lined by tall columnar cells bearing long cilia and in each enclosing a lumen of considerable size filled with seminal secretion.

An interesting subject—namely, the mechanism by means of which the seminal secretion is conveyed from the seminal tubules to the epididymis—may well be referred to here. The seminal tubules have, as is well known, no sheaths of muscular tissue to exercise a compressing influence upon them and so expel their contents, as is the case with the tubules of most other glands—those of the prostate, for example. Moreover, the testicle itself has only a very imperfect covering of striped muscle in the form of the cremaster, which is a suspender rather than a compressor of the body of the testis. Accordingly, in the absence of any such muscular mechanism, either around the individual seminal tubules or around the whole gland, we are left to assume that the secretion is forced out of the seminal tubules by the *vis a tergo* pressure under which it is produced, and that as new secretion is formed the older material is forced along the tubules into the channels of the rete, thence into the vasa efferentia, and ultimately into the tubules of the upper end of the epididymis. These last have muscular walls which by their contraction must drive the seminal secretion onwards; and, besides, these tubules are lined by ciliated cells which are presumably for the purpose of driving the secretion onwards.

3. *In the aged.*—The time at which the testes cease to produce their special secretion—the spermatozoa—and the person loses his reproductive powers varies within a wide range. In some men between the ages of seventy and eighty years the seminal tubules may be found active—that is, showing spermatozoa and the different stages requisite for their production; and it is known that men about or over eighty years of age may beget children. Some men suffer from spermatoceles at an advanced age, in whom the production of spermatozoa must be still going on, for in the fluid removed from such spermatoceles during life there are usually numerous active and vigorous sperm cells lashing their tails and moving swiftly from place to place. On the other hand, the testes may, independently of disease, cease to produce spermatozoa at as early an age as fifty, and may undergo at that time the structural changes which I have elsewhere more fully described as characteristic of the natural involution of this organ.² I may here simply state that in the testicles of the aged two distinct stages may be recognised in the process of involution or decay to which they are liable. In the *first* the epithelium of the seminal tubules, and also that of the tubules of the globus major of the epididymis, undergo more or less complete fatty degeneration and partly disappear, and the tunica propria of the tubules of the testicle

FIG. 3.

Asymmetrical testes in a man aged forty-four years.
A, Right. B, Left.

structure, the left was stunted in its growth and the right overgrown.

The seminal tubules, which in the adult are large and much convoluted, are composed of a thin tunica propria lined by the seminal cells. The tunica propria usually consists of a single layer of flattened connective-tissue cells, and is, therefore, less obvious than the corresponding structure in the seminal tubules of the boy's testis. Immediately within this is a continuous layer of small cubical cells, which are the parents of all the others. The next layer consists of two or three strata of large polygonal-shaped cells with large nuclei, which are usually found in one or other of the stages in the process of division. More centrally still—that is, nearest to the lumen—are two kinds of cells not usually arranged in definite strata: the one in which young spermatozoa radially disposed are found, and the other in which the nuclei are broken up into fragments, probably preliminary to their escape into the lumen after the dissolution of the protoplasm of their containing cells. These nuclear subdivisions do not, so far as I have observed, undergo any further change so as to develop into spermatozoa. Thus, the central cells in an adult active

FIG. 4.

Section of the tubules of the epididymis of an adult. $\times 350$.

seminal tubule are of two kinds—viz. the one which gives rise to the young spermatozoa, and the other which after subdivision of its nucleus undergoes dissolution and probably contributes the greater part of the fluid portion of the seminal secretion before the latter leaves the seminal tubules. The central lumen of the tubule is occupied by fully formed spermatozoa, some fluid secretion, and some degenerated cells

¹ This has been to some extent worked out by Frazer. See Quain's Anatomy, vol. II., ninth edition, p. 689.

² Journal of Anatomy and Physiology, vol. xxvii., p. 474.

becomes somewhat thickened, but the intervening intertubular connective tissue remains practically unaltered. In the epididymis the muscular wall of the tubule is replaced by fibrous connective tissue, and the intertubular connective tissue is increased, dense and fibrous. In the other, or second, stage the seminal tubules are much reduced in size, the epithelium having in great part disappeared, leaving only in many instances a single layer of long, tapering, columnar cells, lining and filling the tubule, the central spermatozoa-producing cells having completely disappeared, while the tunica propria is greatly thickened from proliferation of its own connective-tissue cells and the formation of a fibrous matrix. The intertubular connective tissue is in this second stage relatively increased owing perhaps to the diminution in the size of the seminal tubules; but it still remains of loose texture, and contains, as in the normal state, many connective-tissue cells. The epididymis shows no other changes than those incidental to the first stage. Besides the above there is a third change, which is more

FIG. 5.

Left testis of a man aged seventy-six years. Natural size.

partial, and much resembles the result of the inflammatory process. It is usually observed in the small or shrunken testicles of old men and affects both organs. In the altered patches the seminal tubules, in the majority of instances, are completely transformed into fibrous rods or cords; but in some there still remain in the central fissure that represents the original lumen traces of epithelial cells derived from the degenerated cells of the tubes. The intertubular connective tissue is increased in amount and converted into a dense fibrous variety. It will be observed that in the senile testicle the tubules do not seem to become dilated or to form cysts, as is commonly the case in the prostate and some other glands. Thus the testicle passes through certain phases in its life-history. It acquires its full size and full function at the time of puberty, maintains this for a long period of years—it may be up to from seventy to eighty years of age,—and then declines or undergoes natural involution or decay, the period at which decay sets in varying in different persons.

Briefly, we may summarise the different phases in the life-history of the testis thus. 1. In the boy the seminal tubules are composed of solid rods of epithelial cells, supported by a relatively large amount of cellular connective tissue sufficient to give firmness to the structure of the gland. 2. In the adult the seminal tubules are much larger, are actively producing spermatozoa, and have relatively very little loose areolar tissue supporting them, the tubules being in consequence easily disentangled from one another. 3. In the aged, when involution has taken place, the seminal tubules are much reduced in size, the inner epithelial cells having, from fatty degeneration and subsequent disintegration, entirely disappeared, leaving only the peripheral layer of cells, which are often liable to elongate and to become fibrillated in their long axis. The intertubular connective tissue is relatively increased, and the tunica propria of the tubules is usually thickened. Similar changes take place in the tubules of the upper end, globus major, of the epididymis.

These changes agree, in so far as the thickening of the walls of the tubules and of the intertubular connective tissue is concerned, with the changes which the mammary and other glands pass through when their function ceases, but, as I have just stated, the tubules do not become dilated or cystic.

THE EFFECT OF CELIBACY UPON THE TESTIS.

The effect of long celibacy upon the spermatozoa-producing power of the testis is one of considerable interest, and one upon which the medical man is not infrequently consulted. Under these circumstances the organs are usually smaller and softer than they are in a married man of the same age; and it would appear that the sexual desire is under such circumstances commonly in abeyance. So far as I am aware, it has never been determined microscopically to what extent, if any, the structure of the seminal tubules suffers from long celibacy. The bodies of the testes commonly become reduced in size, soft, and flabby, yet we know that under the natural stimulus they in a comparatively short period of time regain their full size and full function, with the production of spermatozoa. It may, therefore, be assumed that atrophy does not occur, but merely that the organ becomes slightly reduced in size, the capability of the seminal cells of the tubules of the testis to multiply and to produce spermatozoa merely remaining in abeyance until the sexual feelings are aroused and the sexual glands thereby stimulated.

THE INFLUENCE THE TESTICLES EXERT UPON THE GROWTH AND DEVELOPMENT OF THE ACCESSORY SEXUAL GLANDS.

The influence the testes exercise upon the accessory sexual glands (the prostate, vesiculæ seminales, and Cowper's glands) may be inferred from those cases in which the testes (both) were removed in early life. There are many of the domesticated animals in which this operation is performed with commercial advantage, and in some countries the same is done in man in order to produce the eunuch; indeed, among a certain sect of people in South-east Russia removal of the testes late or early in life is a practice religiously observed and enforced. The prostate gland is essentially glandular in structure, and the muscular tissue which is abundant in it is apparently for the purpose of expelling the secretion from the tubules into the ducts and so into the prostatic dilatation of the urethra. In the full-grown eunuch the prostate gland is small, atrophied, and fibrous. The glandular tubules, having never fully developed, are represented only by branching fissures, which are obviously the representatives of the ducts, and are lined by a single layer of flattened cells. The intervening or intertubular connective tissue is relatively increased in amount, and consists almost entirely of fibrous connective tissue, with hardly any of those unstriped muscular fibres which are so abundant and form so large a proportion of the intertubular connective tissue in the normal, fully developed gland.³ The vesiculæ seminales are small and their sacculi are devoid of secretion. Cowper's glands are small, fibrous, and in much the same state as the prostate gland. The penis is small, and the sheet of striped muscle around the intrapelvic part of the genital portion⁴ of the urethra (including the external sphincter of Henle and the constrictor urethræ) is small, pale, and fibrous, instead of being thick, well-formed, reddish-striped muscle. The special muscles of the penis, and with them the accelerator urinae, are also small and ill developed. The same influence is exerted by the absence of testes in other animals—e.g., in the dog, in the cat, in the horse, in the bullock, and in the boar. In the last animal the prostatic and Cowperian glands, together with the striped muscle of the urethra, are so pronounced in the entire male and so diminutive in the castrated pig that the contrast between them is very striking. In the entire animal, indeed, these glands are so prominent, and in the natural state so enormously developed, that they deserve special notice. The prostate is bilobed and lies on the sides and behind the urethra. Each lobe is composed of numerous

³ With regard to the enlarged prostate in old men, removal of the testes, whether they be at the time of their removal actively engaged in the production of spermatozoa or in one of the stages of involution already referred to, produces a similar effect—namely, atrophic changes in the gland tubules and in the intertubular connective tissue, which soon take place. The gland steadily diminishes until it becomes reduced to a small size. For the early changes in the enlarged prostate after castration see a case reported by me in the *British Medical Journal*, March 9th, 1895.

⁴ By the genital portion of the urethra I mean that portion which extends from the opening of the vasa deferentia forwards to the end of the penis. The reasons for this nomenclature are given in a paper entitled "Observations on the Urinary Bladder and Urethra" (*Journal of Anatomy and Physiology*, vol. xxv., p. 535, 1891).

small glandular lobules held together by loose areolar connective tissue, which in the form of a thin sheet surrounds and thus binds together the different lobules making up each lobe, and the gland is soft and granular. Its ducts pass into the hinder, or dorsal, wall of the urethra. It is composed mainly of vesicles, some of which are quite small and hardly visible to the naked eye, others being large and one-sixth of an inch in diameter; and they are filled with a thin, slightly turbid mucous secretion. Each vesicle is lined by a single layer of cubical or subcolumnar epithelial cells. The vesicles are embedded in a thin layer of tissue, mainly composed of unstripped muscular fibres, and traversed by blood-vessels, lymphatics, and nerves. Cowper's glands also are very large, each measuring four and a half inches in length, and at the lower and larger end one and a quarter inches in thickness. They are firm, elongated, three-sided pyramids, lying one on either side of the urethra, and having over the hinder part of their outer surface, and all over the dorsal, or posterior, surface, a sheet of reddish-striped muscle with the fibres running from behind outwards and forwards on to the dorsum. In the middle of each is a large dilated branching duct into which smaller ones open. The smaller ducts commence in the glandular substance proper, which is subdivided by thin fibrous partitions into small compartments. The main duct narrows as it passes out at the posterior extremity of the gland, rendering it probable that the main duct, and also the smaller ducts, act as reservoirs for collecting and retaining the secretion of the gland, which is thick and viscid. The ultimate gland lobules are composed of numerous small vesicles lined by a single layer of columnar cells lying on a basement membrane which consists of a single layer of flattened connective-tissue cells. The columnar cells have small nuclei near their attached ends, and their protoplasm is clear and almost transparent. The vesicles are separated from one another by the minimum amount of connective tissue without unstripped muscle fibres in it. Cowper's gland thus differs from the prostate in having no unstripped muscle in its substance and in having a thick sheet of striped muscle partially covering the gland on its outer surface, which serves the purpose of expressing its secretion. The sheet of striped muscle around the intrapelvic part of the genital portion of the urethra is thick, of red colour, and well formed. The muscular fibres are of full size, and they present the usual structure of normal striped muscular fibres.

In a full-grown pig, which when a few days old was deprived of the testes, the condition of the parts presents a striking contrast. The prostate is represented by two small, flat, bean-like masses, which are firm and composed of small compact lobules held together by means of loose areolar tissue. Each lobe is one inch long, and one-third to one-fourth of an inch broad. Each lobe is composed of a number of tubules with thick walls, consisting in the main of fibrous connective tissue with a few unstripped muscular fibres, and lined by a single layer of subcolumnar cells. In many of the tubules there is a small lumen, but in others the interior is filled with cells. The tubules in a lobe are connected together by somewhat dense fibrous connective tissue, though the lobules themselves are connected only by a small amount of loose areolar connective tissue. Cowper's glands are small elongated pyramids. They measure two inches in length and one-fourth of an inch in thickness at the lower and larger end. The striped muscle on their outer surface is correspondingly small. They are mainly composed of ducts which are filled with a mucous secretion. The peripheral part of the gland is composed of numerous closely packed vesicles which have hardly any lumen and are lined by a single layer of subcolumnar cells with clear protoplasm. The sheath of striped muscle around the intrapelvic portion of the urethra is thin and fibrous, and the muscular substance is pale. The individual muscular fibres are of small size and about half the size of those in the same muscle in the boar. The contrast between the accessory sexual glands in the boar and the same glands in a pig castrated when young clearly shows that the testes exert an all-important influence upon the growth and development of the accessory sexual glands, and that the full development of the striped muscle around the urethra is dependent upon the existence and full development of the testes.

THE INFLUENCE THE TESTES EXERT UPON THE GROWTH AND DEVELOPMENT OF THE BODY AND THE MIND.

Not only do the testes—the dominating sexual glands—exert a marked influence, as has been shown above, upon the

growth and development of the accessory sexual glands, and upon the growth of the penis and the striped muscle around the urethra, but they also exert an important influence, as is well known, upon the growth and development of the body, and doubtless upon the mind. If a boy when young be deprived of his testes—castrated—the developmental changes that go on to form the characteristic features of man do not take place, and, as he is sexless, characters that are more or less intermediate between those of man and those of woman develop; indeed, such a person, commonly known as a eunuch, acquires characters that are more akin to those of the female than those of the male. The female likewise, we know, when deprived of ovaries acquires some of the characteristics of the male. John Hunter noticed the development in the hen pheasant of fine and brilliant plumes after disease involving and destroying both ovaries. The eunuch is usually large, fat, and flabby, with scanty hair on the face. His pelvis is broader and his shoulders are narrower than those of the entire man; his features simulate those of the female, but are not so well cut or so delicately shaped, being, like the rest of the frame, coarser. His voice remains like that of a boy—that is, in the high register—though the larynx enlarges somewhat, and the vocal cords increase in length. Eunuchs are in great requisition in the choirs of some churches for their voices, which combine the sweetness of the soprano and the richness of the tenor notes. Precisely the same changes take place during puberty in persons in whom the testes are diminutive and their special structure is wanting. Such persons I have termed "eunuchoid," because they resemble eunuchs in all particulars save and except that the testes have not been removed, but remain in a diminutive or abortive condition. The effect of the removal of the testes in early life upon the development of the mind at puberty is a subject which is scarcely ripe for solution. What is written about eunuchs is unreliable, chiefly because they as a class have always been despised by men, and whatever has been said of them has been too highly coloured by prejudice. Many of them have attained to high rank and position and have shown great capacity for transacting business of all kinds. One of their number, Narses, was among the first generals of the Roman Empire. He not only possessed great power over his soldiers and was the foremost in the practice of war tactics, but was also highly esteemed and respectfully feared by them. Another celebrated eunuch was Eusebius, who possessed, in addition to other powers, that mental quality which eunuchs have always been noted as developing and exercising in the courts of eastern countries—namely, that necessary for the purposes of intrigue. Other eunuchs who have taken a prominent position in the world's affairs might be mentioned. Further information upon this subject is still wanting, for though we know in what respects a eunuch resembles the woman and differs from the man physically, yet we do not know to what extent the mental characters correspond and resemble those of women and differ from those of man. Additional and critical observations, indeed, are still needed for the elucidation of this not uninteresting problem. I need scarcely allude to the difference between the gelding and the entire horse, and between the bullock and the bull, to indicate the effect of removal of the testes upon the body. In some animals, as the cat, these differences are not so marked.

THE EFFECT OF REMOVAL OF THE TESTES IN MEN AND IN FULLY GROWN ANIMALS.

Removal of the testes in an adult and in fully grown animals produces in a comparatively short time (within three months) atrophic changes in the accessory sexual glands—the prostate, vesiculæ seminales, and Cowper's glands. These parts after a time acquire a structure that is similar in all respects to the structure of the same parts in a eunuch or in a eunuchoid person. In the latter the condition arises from arrested growth and development, whereas in the adult deprived of the testes it arises from atrophy and disappearance of existing structures. The result is the same in each, but the process differs. In adults deprived of their testes the body will have acquired the male characteristics, and in consequence the permanent skeletal parts will be but slightly, if at all, modified. Such persons, however, usually put on fat and get, in fact, into better condition. They often, also, become placid and content, though in some cases, as in the young man whose testes were removed by Sir Astley Cooper, extreme misery may ensue.

LECTURE II.

Delivered on March 27th.

RETAINED TESTES.

MR. VICE-PRESIDENT AND GENTLEMEN,—In the first lecture an account was given of the changes that the structure of the testis undergoes from early life to old age, and of the influence, in addition to producing spermatozoa, that this organ exercises upon the development and growth of the accessory sexual glands, and also upon the formation of the male sexual characteristics. To-day, after reviewing the position the testes occupy in different animals and in man, I propose to give an account of the structure of the testes when they fail to reach the end of their destined course, and to point out the function, if any, which the testes under such circumstances are capable of performing.

In the study of the comparative anatomy of the male generative organs in the mammalian group of vertebrates there is nothing, perhaps, more striking than the varied permanent positions that the testes occupy in the several classes or groups of animals. In the Monotremes, in the Elephant, and in the Cetacea the testes remain in the abdominal cavity just below the kidneys; in a few artiodactyls they are found in the groin; and in the remainder, which comprises the majority, they occupy the dependent scrotum, be it inguinal or perineal.⁶ Further, in the rutting animals, such as the hedgehog, the testes are found in the groin during the rutting season and are withdrawn into the abdominal cavity at the end of that period, where they remain until the return of the next period of rut. Thus, in these rutting animals the testes pass outwards into a sac of peritoneum—the tunica vaginalis—in the groin at the onset of the rutting season, and backwards into the abdominal cavity at its termination; and, as will be pointed out later, these organs only attain their full size and full function when they reach the furthest point in the course of their descent, dwindling and losing their spermatozoa-producing powers when withdrawn into the abdominal cavity. The testes, then, occupy—(1) in some animals a permanent position in the abdominal cavity below the kidneys; (2) in others they occupy at all times the scrotum, be it inguinal or perineal—the serous cavity may or may not then be shut off from the general peritoneal cavity; and (3) in others (rutting animals) they are in the scrotum during the period of sexual activity (rut) and in the abdomen during the period of sexual inactivity (non-rutting period). John Hunter, in his well-known monograph on the Position of the Testes in the Fetus, gives an account of the place of origin of the testis and describes the mechanism by which, in part at any rate, it is made to travel from its protected and concealed to a more unprotected and exposed position. He notes that the mechanism not infrequently fails, both in man and in the domesticated animals, to convey the organ to the termination of its destined course—the scrotum. The testes on one or both sides may fail to pass out of the abdominal cavity or to go beyond the external abdominal ring. The commonest situation in which an undescended testis is found is the external abdominal ring; it may pass into the perineum, thus missing the scrotum. More rarely it finds its way into the upper and front part of the thigh.⁷ It may also be found in the cavity of the pelvis. Failure in descent of the testis is more common on the right side than on the left, as was shown by Braman. When one testis only remains undescended—whether the organ be in the abdominal cavity, at the internal abdominal ring, or in the groin, the other being in its natural position and well developed—the case is of interest chiefly owing to the concurrence of congenital hernia in connexion with the undescended testis and the difficulty of successfully applying an apparatus for the proper closure of the canal and the prevention of the escape of intestine. If, however, the surgeon finds it impossible to adapt a well-fitting and comfortable truss,

then the question of operative measures may arise, and naturally the exact structure of the testis, its capabilities of producing spermatozoa, and the influence it may exercise upon the man become of importance. Especially is this the case in those instances, which are not very rare, of incomplete descent of the testes on both sides. When the testes are duly transmitted they acquire, as is well known, their full size and full function; but when they fail to reach their destination they do not attain either their full size or their full function—the production of spermatozoa. This may appear strange, seeing that the testes do in some animals attain their full size and full function when retained in the abdomen or in the groin. It is, however, the fact that, in any given animal in which complete “descent” of the testis normally takes place, the testis, in order to attain its full size and full function, must reach and occupy the terminal part of that destined course. In man, for example, unless the process of descent be fully accomplished the testes attain neither their full size nor their full functional powers. I am aware that this has been doubted, but my own observations quite confirm the view. Further, I have shown in a paper entitled “The Structural Changes in the Testicle of the Dog when it is Replaced within the Abdominal Cavity”⁸ that when the testis in the dog is by experiment replaced within the abdominal cavity it soon dwindles and loses its spermatozoa-producing powers, undergoing at the same time certain definite retrogressive changes in the structure of its seminal tubules.

The following is the only example of a retained testis in a boy that I have had the opportunity of examining. He was aged twelve years, and the right testis was just outside the external abdominal ring. There was apparently no gubernaculum extending to the scrotum, which was on that side small. The body of this, the right testis, measures 14 mm. in length by 8 mm. in breadth, whereas that of the left testis, which was in the scrotum, measures 15 mm. in length by 10 mm. in breadth. The right epididymis is small and apparently deficient in its lower part. The right vas deferens is short and slender, but otherwise natural. In this, as in similar cases, the tunica vaginalis is large, and the processus vaginalis is patent, opening freely above into the peritoneal cavity and below into the capacious tunica vaginalis. The seminal tubules are small and filled with small epithelial cells, as they are before puberty.

When the testicle of a puppy is replaced in the abdominal cavity it undergoes but little change, becoming only slightly less plump than its fellow. It continues to grow with the body until the onset of puberty, but its growth is not so great as that of the undisturbed organ in the scrotum. (See Fig. 6.) At puberty it does not pass through the

FIG. 6.

Testicles of a small fox-terrier. The right is of natural size and descended, the left of small size and undescended (in groin).

structural changes preliminary to the formation of the mature spermatozoa-producing tubules, as does its fellow, the descended organ; nor does it remain stationary, retaining its pre-puberty structure, but it undergoes a change that is peculiar to a retained or replaced testis, the seminal tubules becoming altered. They are of small size and have only a small central lumen, and are lined by a single layer of delicate columnar cells, which are derived from a modification of the single layer of the peripheral cubical cells

⁶ In all the animals, with the exception of man, and, I believe, the chimpanzee, the connexion between the peritoneum and the tunica vaginalis remains as a patent canal into which the vas deferens and the spermatic vessels and nerves more or less project, carrying the peritoneum before them. In man and in the chimpanzee—the only two vertebrates which assume the erect posture—this connexion is obliterated at or soon after birth.

⁷ In fox-terriers, which are now so highly bred in this country, failure in descent of the testis on one side is not at all uncommon, and it is well known that this condition not infrequently happens in horses. The entire horse with one testicle descended and the other retained within the abdominal cavity is so common as to be known as a “rigg.”

seen in the normal state before and after puberty, the central cells having disappeared. (See Fig. 7.)

Thus the seminal tubules in the testis replaced in the abdominal cavity, are incapable of producing spermatozoa. They undergo, indeed, a degenerative change, being no longer like the tubules which characterise the pre-puberty state of the testicle, inasmuch as they no longer

FIG. 7.

Section of seminal tubules from left undescended testis of dog.

remain solid, but the central cells disappear, while the peripheral ones are converted into a layer of columnar cells which taper, towards the lumen of the tubule.

UNDESCENDED TESTIS IN THE ADULT.

I come now to the account of the undescended testis in the adult man and in the full-grown dog. There is a specimen (1065) in the Pathological Museum of the University of Cambridge, the description of which in the catalogue is as follows: "Right testicle situated at the external ring. It [testis] is small, though plump, and the epididymis is disproportionately large. There is a sac of a congenital hernia,

FIG. 8.

Right undescended (in groin) testis of a man, natural size. T, Body of testis. A, Appendix. ep, Epididymis. V.D., Vas deferens.

from which a blue glass rod has been passed into the tunica vaginalis. The left testicle is of natural size and occupied the natural position in the scrotum. On microscopical examination, after the specimen has been some months in spirit, large cells, like sperm cells, are found in the epididymis on both sides, but spermatozoa in the left only." The body of the right testis measures 3 cm. in length by 1.8 cm. in breadth, whereas that of the left measures 4.5 cm. in length by 3 cm. in breadth. A section of the right testis shows the seminal tubules to the eye, as in a normal organ, but they are more distinct, and, therefore, more easily seen, the intertubular connective tissue being relatively increased. Under the microscope the seminal tubules in this right testis are found to be reduced to at least one-half their natural size, and the intertubular connective tissue is relatively increased. This intertubular tissue is composed in the main of spindle-shaped connective tissue cells, with but little intervening fibrous matrix, and in it there are hardly any traces of the peculiar interstitial cells frequently found in the normal and full-grown organ. The seminal tubules are, in addition to being reduced in size,

altered in their structure. The tunica propria is much thickened and as seen in transverse section forms a sort of collar round the tubule. This tunic is composed, as in the natural condition, of two or more layers of flattened connective-tissue cells, with but little intervening fibrous matrix, the thickening seen in the specimen being mainly due to the formation, on the side next the lumen, of a layer of newly formed, almost transparent, fibrous tissue, with only one

FIG. 9.

Section of seminal tubules of an undescended testis in an adult man. x 350.

or two flattened cells embedded in the matrix. This layer of tissue I have often found, and always in the same position in other cases of atrophy. The epithelial cells in the seminal tubules are greatly reduced in number, and in the majority of instances the cells form only a single layer, which lines the thickened and altered tunic and which

FIG. 10.

Section of seminal tubules of an undescended testis in an adult man. Tunica propria much thickened and epithelium atrophied. x 350.

encloses a small central lumen. The cells differ from the normal, inasmuch as they are of columnar shape, with broad bases and narrow free extremities which project into the interior of the tubule and bound the central lumen when present. In each of these cells a round or ovoid nucleus may be seen occupying a position near the basal or attached

end of the cell, and in each the protoplasm is finely granular, with a tendency to fibrillation in the long axis of the cell. Here and there among these cells smaller cells, with irregular outlines and indistinct nuclei, may be seen. In a few of the tubules the epithelial cells are not so regularly arranged, but they are of irregular outline and are massed together, as it were, there being no central lumen. In none of these tubules is there any evidence of spermatogenesis in the epithelial cells, and there is no evidence of spermatozoa in the interior of the tubules. In short, the seminal tubules are small, their tunica propria is thickened, and the epithelium is reduced to a single layer of columnar-shaped cells. I have examined several others in which the structural condition of the tubules was similar to the above.

THE RETAINED TESTES IN THE DOG.

In a dog three to four years old the right testis was found in the groin just beyond the external abdominal ring. It was small and measured 15 mm. in length by 12 mm. in breadth. The left testis, which was in the scrotum, was of full size, and its body measured 20 mm. in length by 15 mm. in breadth. With the naked eye the only difference observable was that the tubules were more apart, and therefore more distinct in the retained organ. The seminal tubules are not more than one-half the size of those in the left or descended organ. In each tubule the tunica propria is somewhat thickened, the cells being columnar and tapering and completely filling the tubule. This difference from the normal is very marked.⁹ There is no evidence of spermatozoa or spermatogenesis.

Thus, both in man and in the dog the retained testes are of small size; they alike present a definite structure that is almost, though not quite, peculiar to them; and they are not in that state which is fitted for the production of spermatozoa. Hunter expressed the view that the retained testes were, *ab initio*, imperfect in their structure, and that it was owing to this imperfection that they failed to stimulate into activity the mechanism of descent, and thus they remained undescended. Curling stated that this was not the case in the majority of instances, and he considered that the testes when retained are in structure like the testes before the onset of puberty. That this view, however, is not correct is shown by a comparison between the structures of the retained and of the undeveloped organ. In the former, as we have seen, the tunic of the tubules is thick, and the epithelial consists, as a rule, of a single layer of columnar cells; whereas in the normal condition of the child the tubules consist of solid rods of small polygonal cells, and each is surrounded by a thin tunica propria. Godard, who is followed by Monod and Arthaud, maintains that the retained testes acquire their natural structure, but he specified that their secretion does not contain spermatozoa. A careful microscopical observation would, however, have shown him that, although to outward appearance the testes in the two cases (descended and retained) are similar, the intimate structure is very different. Follin and Goubaux, with whom I concur, found that both in man and the domesticated animals, not only were the undescended testes of small size, but the seminal tubules were atrophied and incapable of producing spermatozoa.

Further, if a properly descended testis of a dog be replaced in the abdominal cavity without injury to the structures of the cord it undergoes similar changes, as may be gathered from the result of the following experiment in a fox-terrier three months old. On May 22nd, 1891, the left testicle, which measured 15 mm. in length by 12 mm. in breadth, was replaced in the abdominal cavity. At the beginning of October in the same year the right testicle, which had not been interfered with, began to show signs of growth, and by the beginning of March it had reached its full size. The dog was killed on March 9th, 1892 when the right testicle measured 30 mm. in length by 20 mm. in breadth, this being the usual size for a grown-up dog of this breed. The left testicle was found attached to the peritoneum at the brim of the pelvis, and hanging down into that cavity; the vas deferens was coiled, but the spermatic vessels, though somewhat smaller than those of the opposite side, were normal and not in any way interfered with in their course. The body of the testicle measured 17 mm. in length and 13 mm. in breadth, and was small and roundish, but of natural appearance, though softer than its fellow. The epididymis was small though relatively larger

than the testis, as is usually the case in young animals. The tubules in the left testicle were only about one-half of the size natural in a full-grown organ. The tunica propria of each tubule was somewhat thickened, and the tubules were widely separated from one another. The epithelial lining of these tubules was composed of a single layer of columnar cells resting upon the inner surface of the tunica propria. These cells contained large, round, clear nuclei, which were found near the basal or attached ends of the cells; their protoplasm was delicately fibrillated in the long axis of the cells and was

FIG. 11.

Section of seminal tubules of a testis of a full-grown dog replaced in the abdominal cavity thirty days before death. $\times 450$.

comparatively free from granules, as in Fig. 12. The cells themselves were prolonged to the centre of the tubule in fine converging processes composed of the delicately fibrillated protoplasm of the cells. There were no spermatozoa, or any trace of their formation, in any of the tubules. The tunica albuginea of the testicle, together with the septa and the intertubular connective tissue, were not changed beyond a relative increase due to a diminution in the size of the seminal tubules. In the epididymis the tubules were small and contracted, but they were all lined by the usual single layer of columnar epithelial cells bearing fine long cilia. In

FIG. 12.

Section of seminal tubules of a testis of a full-grown dog which was replaced in the abdominal cavity three months before death. $\times 350$.

the central lumen, which was correspondingly small, there were no spermatozoa, but in their place a few coarse, clear granules. The right testicle and epididymis were normal. In the seminal tubules there was abundant evidence of the formation of spermatozoa, the tunica propria being lined by cubical cells; the cells nearer the lumen, which were altogether absent in the left testicle, showed the division of their nuclei preparatory to the formation.

N 2

⁹ See, further, a paper by me in the Journal of Anatomy and Physiology, vol. xxvii., p. 483.

of spermatozoa; and in the tubules of the globus major of the epididymis there were numerous spermatozoa.

It appears, therefore, that:—1. The retained testis in a man and in the domesticated animals is of small size, and the seminal tubules, though smaller, are more distinct, owing to the disproportionate amount of intertubular connective tissue. 2. The retained testis in a boy is of smaller size and is softer than its fellow which is in the scrotum. When the normal testis of a puppy is replaced in the abdominal cavity it dwindles a little and becomes softer than natural, and fails to grow as its fellow left undisturbed in the scrotum. The walls of the tubules in the retained testes of a man are often thick from the formation of fibrous tissue on the inner surface of the tunica propria, and there are no traces of spermatogenesis. 3. The testes do not acquire their full (spermatozoa-producing) function unless they reach and remain at the point of descent furthest from their primary position. 4. The testicle of a full-grown animal, when replaced in the abdominal cavity soon dwindles to two-thirds or one-half its natural size and presents precisely the same structure as does the replaced testicle of a young animal.

It may be well to give briefly an account of the testicle during the non-rutting period in a rutting animal, and to compare with it the undescended testis of man. For this the

FIG. 13.

Testis of full-grown hedgehog in mid-summer. Natural size.

hedgehog, an animal that is procurable at any time, will serve our purpose. In *mid-summer*, when the rutting season is at its height, the testis of the hedgehog is of full size,

FIG. 14.

Section of seminal tubules of hedgehog in mid-summer. $\times 300$.

measuring 25 mm. in length by 15 mm. in thickness from before backwards. The tunica albuginea is tense, and the contained structures are soft and at once bulge through an

FIG. 15.

Testis of full-grown hedgehog in mid-winter. Natural size.

incision in it. The seminal tubules are large and the epithelial cells are actively engaged in the production of spermatozoa

and seminal secretion, which fill and occupy the somewhat large central lumen. In *mid-winter* the testes are in the abdomen and of hardly half the size they attain in summer, measuring 15 mm. in length by 10 mm. in thickness from behind forwards. Their structure is firmer and does not bulge on section of the tunica albuginea. The seminal tubules are much reduced in size and are composed of solid rods of epithelial cells arranged as follows. At the periphery there is a single and continuous layer of small cubical cells with

FIG. 16.

Section of seminal tubules of testis of hedgehog in mid-winter. $\times 300$

round nuclei and granular protoplasm. Within these are numerous irregular-shaped cells with round nuclei and a large amount of granular protoplasm. Many of these cells are vacuolated. In a few of the tubules there still remains a central lumen, but in none of them is there any trace of the formation of spermatozoa. Thus, the seminal tubules of the testes in *mid-winter* correspond on the whole with those of the undeveloped testes in man and in the dog. The seminal cells are quiescent and show no signs of the formation of spermatozoa.

THE EFFECT OF THE UNDESCENDED TESTES UPON THE GROWTH AND DEVELOPMENT OF THE BODY.

It is of much interest to find that the undescended testes, though incapable of producing their special secretion of spermatozoa, yet are capable of exerting their peculiar and important influence upon the growth and development of the body. When only one testis fails to "descend" to the termination of its destined course, the opposite organ having duly reached the scrotum, the person grows, as we often have the opportunity of observing, just as if both organs were in their natural position. The fully descended testicle produces spermatozoa in abundance and usually acquires a larger size than natural, due to what is called "compensatory hypertrophy." Thus, a person who has one testis natural and in the scrotum, whether the opposite be undescended or absent, is in possession of full virility. But when both testes fail in their descent they, as we have just seen, are incapable of producing spermatozoa, and in consequence the person is sterile. In spite, however, of the imperfection of the organs, such a person acquires all the external bodily characteristics of the male and is in all respects, except in the power of procreating, like an ordinary man. His shoulders are broad, his pelvis is narrow, his beard and moustache and hair on the pubes are well grown, his voice is deep and manly, and his penis is large and well developed, though the scrotum is small and empty; so that the external appearance, except that of the scrotum, would give no clue to the condition. I know of one such person who is well formed and who is capable of erection and emission, but without issue. It is evident, therefore, that the influence of the testis upon the growth and maintenance of the characteristics of the male is a property independent of their power of producing spermatozoa; and the remarkable fact is established that the spermatozoa-producing work of the testes, possibly even their potentiality for that purpose, is not necessary for the establishment of the influence which those organs exert upon the rest of the body. It is further of interest that, although the natural involution of the testis in the aged is unaccompanied by any corresponding change in the system, yet if the testes in an elderly person are removed the accessory sexual glands, at any rate, are found to undergo changes somewhat similar to those which are observed in eunuchs and in eunuchoid persons.

The function of the testes is, therefore, clearly twofold—viz. (1) to control and determine the development of the characteristics of the male sex, and (2) to produce spermatozoa for the reproduction of the species. These two functions are usually exercised together, but that the former may

be exercised when the latter fails seems to indicate that the production of spermatozoa is the more specialised property and attained with more difficulty. In what manner is this sexual effect of the testes upon the body produced? Is it through the medium of the nervous system as an ordinary reflex, or is it through the medium of some substance produced by the seminal cells (whether they form spermatozoa or not) and absorbed into the system, which by influencing the nerve centres or in some other way controls growth and nutrition? Brown-Séquard tried upon himself, when he was seventy-two years of age, the effect of the subcutaneous injection of a watery extract of the testes of a vigorous dog two or three years of age, and relates that after five daily injections he lost his feebleness, felt many years younger, and was capable of doing more work. The testicle extract has since been used in various diseased conditions, chiefly those associated with nervous debility, but with only temporary results. During the last few years a watery extract of the thyroid gland has been administered with signal success in myxœdema, in which disease the thyroid gland atrophies and ultimately disappears. The disease myxœdema arises from the want of the influence of some unknown substance, which the thyroid gland, as is supposed, elaborates, upon the nutrition centres of the central nervous system. It may be that the testis in like manner elaborates, irrespectively of its spermatic secretion, some chemical substance which by a similar influence not only controls the growth and development of the body at puberty but maintains the manly characters then acquired throughout life.

ABSTRACT OF

The Goulstonian Lectures

ON

THE SUPRA-RENAL BODIES.

Delivered before the Royal College of Physicians of London on March 19th, 21st, and 23rd, 1895.

By H. D. ROLLESTON, M.A., M.D. CANTAB.,
F.R.C.P. LOND.,

FELLOW OF ST. JOHN'S COLLEGE, CAMBRIDGE; ASSISTANT PHYSICIAN
AND LECTURER ON PATHOLOGY AT ST. GEORGE'S HOSPITAL.

LECTURE III.¹

Delivered on March 23rd.

EXPLANATION OF ADDISON'S DISEASE: (1) NERVOUS THEORY; (2) THEORY OF SUPRA-RENAL INADEQUACY (a) AS EXCRETORY GLANDS, (b) AS SECRETORY GLANDS.—TREATMENT OF ADDISON'S DISEASE BY SUPRA-RENAL EXTRACT.

The lecturer recalled the early view as to the absence or unimportance of any function of the supra-renal bodies. This negative view was the physiological basis for the *nervous* theory, which explained the connexion between disease of the supra-renal bodies and the symptoms of Addison's disease by the secondary morbid lesions induced in the neighbouring semilunar ganglia and sympathetic. Thus the languor and collapse were due to the altered condition of the abdominal sympathetic, and the vomiting and pigmentation to the irritation of the sympathetic nerve trunks by the caseous supra-renal bodies. Arnaud and Alexais had accepted this idea, but had limited the nervous changes to the ganglia in the capsules of the adrenal bodies, and had thus been able to explain the fact that in cases of Addison's disease the solar plexus &c. were sometimes quite normal. A modification of the earlier nervous theory was that there need not be any change in the adrenal bodies as long as there was some lesion of the sympathetic. Changes in the supra-renal bodies had even been thought to be trophic in nature and due to injury of the sympathetic. The lecturer said the nervous theory was untenable, since (1) in some cases of Addison's disease the abdominal sympathetic was normal, and (2) Addison's disease was occasionally due to simple atrophy of the supra-renal bodies without any inflammatory change around them. Moreover, chronic irritation of the abdominal sympathetic due to other causes, though it might be associated with pigmentation, did not give rise to Addison's disease.

The theory of supra-renal inadequacy assumed functional activity on the part of these glands. Interference with this function led to an altered condition of the body fluids, in-

cluding the blood; hence this theory might be called the *chemical* theory in contradistinction to the *nervous* one.

BEARINGS OF MORBID ANATOMY ON THE THEORY OF SUPRA-RENAL INADEQUACY.

Destructive tuberculous lesions and atrophy of the supra-renal bodies were known to give rise to Addison's disease. But it might be objected: 1. That these bodies were sometimes extensively destroyed by tubercle or new growth without any symptoms of Addison's disease. In answer to this the lecturer said that in such cases the adrenal affection was usually part of advanced disease elsewhere which had killed the patient before the symptoms of Addison's disease had had time to develop. In addition it was possible that compensatory hypertrophy of accessory supra-renal bodies might occur, and that thus supra-renal inadequacy was obviated. 2. That in cases of Addison's disease the supra-renal bodies were found to contain a comparatively small amount of caseous tubercle, perhaps less than in other cases where no symptoms had been present. In reply to this it might be urged that this failure in compensation might be due to inherent want of vitality, concomitant atrophy, or to pressure exerted by the tuberculous material on the efferent vessels of the organ, thus rendering the organ functionless. 3. That in some cases of Addison's disease the adrenal bodies were healthy, but that the sympathetic was involved in adhesions or growths, such as lymphadenoma. It was possible that here again the vessels of the supra-renal bodies were so interfered with that the organs were practically placed outside the circulation. The facts of morbid anatomy were compatible with the theory of supra-renal inadequacy. The question whether Addison's disease was a toxic condition could not be definitely answered in the affirmative, but from a comparison with other chronic auto-intoxications, such as uræmia, pernicious anæmia, and perhaps myxœdema, it appeared probable that it was so. Extended research into the properties of the urine was urgently needed to determine whether the urine in Addison's disease was more toxic than in health. Oliver and Schäfer had found that the urine of Addison's disease was not more toxic than ordinary urine. This observation militated against the view that Addison's disease was a toxæmia. The toxic condition of the blood in animals after removal of the supra-renal bodies, and the analogy with other diseases, suggested a toxic origin. For the present the question should remain open. The symptoms of Addison's disease could be explained as due to toxic influences. The extreme debility might be due to a poison like curare, the gastro-intestinal phenomena to an irritant poison, and the pigmentation to the constant influence of a toxic body on the sympathetic, leading to an altered condition of the walls of the vessels of the dermis, and thus to increased transference of pigment to the epidermis.

FUNCTION OF THE SUPRA-RENAL BODIES.

The lecturer then discussed the nature of the function of the supra-renal bodies. Were they excretory or secretory organs? McMunn's theory that they picked up effete blood pigment and removed it with its accompanying proteids from the blood was criticised. No accumulation of pigment had been found in the blood in Addison's disease, and as the result of experimental removal no such increase had been proved. There was no increase in the urinary pigments in Addison's disease. McMunn had laid stress on the presence of a pigment—urohæmatoporphyrin—in the urine of Addison's disease, which he regarded as evidence that the supra-renal bodies were not discharging their pigment-metabolising function. This observer had, however, found urohæmatoporphyrin in the urine of enteric fever, measles, cirrhosis, &c., where the supra-renal bodies were not specially affected. This detracted considerably from the force of his argument. As a chemical body urohæmatoporphyrin did not exist; it had been shown to be a mixture of a larger quantity of hæmatoporphyrin and a smaller quantity of urobilin. Garrod had shown hæmatoporphyrin to be increased in tuberculous diseases; since Addison's disease was generally tuberculous, any increase of hæmatoporphyrin, if this did occur, would thus be accounted for. Moreover, hæmatoporphyrin was increased in amount in such various conditions as sulphonal poisoning, gout, phthisis, and pneumonia, and its presence had, therefore, no special significance. From these considerations it was highly improbable that the supra-renal bodies had any special action on effete blood pigment. The question whether toxic bodies were normally removed from the blood by the supra-renal bodies and rendered innocuous was then considered. If the

¹ Lectures I. and II. appeared in THE LANCET of March 23rd, 1895.

supra-renal bodies were crushed and left to be absorbed *in situ* no toxic symptoms resulted; therefore they did not contain the poison they might be supposed to excrete. The toxæmia produced by experimental removal of the supra-renal bodies had been shown to be counteracted by the injection of supra-renal extract. If these organs excreted poisons of the same nature as those accumulating on their removal and thus producing toxic symptoms, injection of the extract would only intensify the existing toxæmia. Again, Abelous and Langlois found that experimental removal of the organs gave rise to a toxic effect analogous to that of curare, while Schäfer and Oliver had shown that the physiological effect of the extract was not at all comparable to that of curare. Therefore the body or bodies giving rise to a toxic condition of the blood in "acapsulated" animals were not the same as the active principles of supra-renal extract. There was, therefore, strong evidence that the supra-renal bodies did not remove effete blood pigment or excrete and metabolise toxins, and that their function was not excretory.

THEORY THAT ADDISON'S DISEASE WAS DUE TO INADEQUATE SECRETION BY THE SUPRA-RENAL BODIES.

This alternative view was strongly supported by the observations of Abelous and Langlois and Schäfer and Oliver. The latter observers had found that, while the healthy supra-renal bodies of man yielded an active extract, these organs in Addison's disease provided an extract which was absolutely inert. What was the method of action of this internal secretion? 1. It might possibly antagonise poisons resulting from the general metabolism of the body in two ways: (a) By exerting a ferment-like action on and thus destroying it. If its active principle was a ferment, the activity of the extract would be destroyed by boiling. Moore had shown that, although long-continued boiling abolished the activity of the extract, boiling for some minutes did not have this effect. This view, therefore, was improbable. (b) By directly neutralising the toxic bodies in a manner analogous to the action of an alkali on an acid. Schäfer and Oliver's experiments showed that the extract had a definite physiological effect on healthy animals; hence the secretion did not act merely as a chemical antidote. To prove whether the extract had any action at all analogous to that of a chemical antidote experiments like that of Buchner with tetanus toxin and antitoxin should be made. 2. The secretion might act as a stimulus to the various tissues of the body. The researches of Schäfer and Oliver were in favour of this view. This tonic influence might act—(a) by regulating their nutrition and activity and preventing the formation of any toxic bodies; or (b) by increasing the resistance and defensive powers of the tissues, including the white blood-corpuscles, so that they were thus enabled to resist and to destroy the toxic bodies produced by the metabolism of the body. The latter hypothesis was attractive, but as yet there was not sufficient evidence to warrant any definite opinion.

In conclusion, Addison's disease was due to inadequate supra-renal secretion, but whether the deficiency in this internal secretion allowed a toxic condition of the blood to develop, or whether it led to a general atony and apathy, could not be settled at the present stage of our knowledge.

TREATMENT.

The treatment of Addison's disease by supra-renal extract was yet in its infancy. Dr. G. Oliver had recorded two cases which had reacted in a satisfactory way, in that the pigmentation diminished, nausea disappeared, and weight was gained. The lecturer had had a case of Addison's disease under treatment since June, 1894; pigmentation remained, but nausea and languor had been relieved. It was important to ascertain the appropriate dose of the extract, otherwise its therapeutic value might be discredited from the employment of inadequate quantities. Forty-four grains of the gland in the day were not an excessive dose, though this was about the weight of the medullary parts (the active portions) of both human supra-renals. Artificial gastric digestion did not impair the activity of the extract, so the administration by the mouth was physiologically correct.² Dr. G. Oliver had suggested the therapeutic use of supra-renal extract as a hæmoestatic in purpura, hæmophilia, &c., and in exophthalmic goitre, cyclic albuminuria, diabetes, and in the conditions of vaso-motorial paresis associated with the menopause.

² Schäfer and Oliver: Proceedings of the Physiological Society, March 16th, 1895.

AN OPERATION SUGGESTED FOR SOME CASES OF INTUSSUSCEPTION.

By F. T. PAUL, F.R.C.S. ENG.,
SURGEON TO THE LIVERPOOL ROYAL INFIRMARY.

WHEN the abdomen is opened for intestinal obstruction and an irreducible intussusception is discovered to be the source of the mischief some form of enterotomy or enterectomy is absolutely necessary. It is too often urged that some specific operation is the only right and proper means to adopt under the circumstances; but experience very soon teaches that there is no kind of intestinal obstruction for the relief of which there is only one best method. The varying circumstances of each case should be met by various procedures, and the surgeon should be prepared to meet the many unlooked-for difficulties which appear in almost every laparotomy undertaken for this condition. Cases of acute intussusception in children are a little less fatal under medical treatment than those in which the obstruction is due to other causes. For this reason the majority of them come under the surgeon's hands at a very late stage of the case, and it is unfortunately the rule rather than the exception to find them in a state of collapse and totally unfit for an extensive resection of bowel. In such cases it is simply throwing away the last chance of life to attempt anything more than the establishment of an artificial anus or a faecal fistula. Again, there are other patients in whom the constitutional condition

A, Light metal tube with expanded, rounded ends. B, Incisions in the bowel, and ligature *in situ*. C, Diagrammatic section of invaginated bowel, showing position of tube.

may be better whilst the intussusception itself is hopelessly irremediable from gangrene or some other cause. In such enterectomy is imperative, and one has to decide after removing the damaged bowel whether the patient will have the better chance by immediately approximating the ends or by bringing them out of the abdomen and approximating later. When collapse and gangrene are both present—and they are generally associated—few, I think, would hesitate in deciding upon the latter course; but when the patient is in fair condition these are suitable cases for immediate approximation, and it only remains to determine which method best fits the circumstances present. Fortunately, in many patients the condition is less grave, and in these an operation on the lines first suggested by Mr. A. E. Barker¹ seems to be the best. The object of this short communication is to propose a modification of his method which may possibly prove serviceable in some cases. When the invagination is short and easily brought out through the incision in the outermost or receiving layer of the intussusception Mr. Barker's operation perhaps leaves nothing to be desired; but when the invagination is too extensive for

¹ THE LANCET, Jan. 9th, 1892.

this, and has to be divided *in situ*, the operation certainly has dangers. There are many large vessels in the invaginated mesentery which, being at the bottom of the wound, are difficult to get at, and cannot be readily controlled by sutures as in the slighter cases; also the tendency which the large stump of mesentery has to retract when the weight is removed is so great that the preliminary sutures are liable to tear out, thus releasing the invagination and rendering it necessary to approximate the ends by another method or bring them out of the abdomen. I therefore propose that the surgeon should be armed with a short metal tube made of aluminium and shaped somewhat as in the engraving (Fig. A). The preliminary sutures—very few of which are required—connecting the intussusceptum with the intussusciens and the first incisions are made as recommended by Mr. Barker; then the returning and entering layers are also respectively incised (see Fig. B), and the tube grasped with forceps is pushed into the position shown in Fig. C. A stout silk ligature is now made to surround the intussusceptum just above the incisions in it, and is tightly tied. Finally, the intussusceptum is cut off below the ligature and withdrawn, and the wound in the outer layer is closed in the usual way.

I have not yet had the opportunity of trying this plan, and as one may have to wait indefinitely for a suitable case I make the suggestion public, in order that if any other surgeon is so disposed he may give it a trial. The end aimed at is exactly the same as that attained by other methods; but it seems to me that there are certain advantages, of which the following, if real, are important: (1) a saving of time, as the ligature replaces many sutures and also closes the bloodvessels before they are divided; (2) the operation is practically bloodless; and (3) disengagement of the invaginated stump is impossible, as it is firmly held by the ligature for at least three days.

Rodney-street, Liverpool.

A CASE OF RABIES.

By B. KEMP, M.R.C.S. ENG., &C.,

MEDICAL OFFICER OF HEALTH, HORBURY.

A BOY ten years of age was bitten in the lower lip by a strange dog on Saturday, Nov. 17th, 1894. He at once told his father. The latter and some other men gave chase to the animal, but it got away, and has not been seen or heard of since. The father said it was a black-and-tan sheep dog. He thought it was rather lame and ran in a staggering manner, like a person half drunk. The boy was brought to my surgery about an hour after being bitten. The lower lip was torn quite through, leaving a small gaping wound. I washed and dressed it with boracic acid and inserted one suture, and ordered the wound to be dusted occasionally with boracic acid powder. I saw the patient again on the Monday and Thursday following the day of the accident; the wound was quite healed, and the boy appeared well. I may say that it was not known that the dog was rabid. The patient's mother told me that he went to school after staying at home for a week, and did so until Dec. 8th. During this time he had not eaten so well as usual, and had become thinner, otherwise he appeared to be well. On Dec. 9th he first complained of not being able to swallow food or liquids so well as usual, and of thirst. On Dec. 10th he could not swallow anything, the thirst was worse, and he was now thought to be suffering from cold. He was ordered to have warm applications applied to the throat and to be kept warm in the house. He said his throat was not sore, but felt as if there was something lower down which prevented him from swallowing anything. He slept fairly well in the night. On Dec. 11th the symptoms were the same; a dose of castor-oil was given him by his mother; he swallowed a portion of it with great difficulty and was put to bed at 7 P.M. The boy did not sleep and awakened his mother about 3 A.M. on Dec. 12th by calling out. He was now very restless, looked wild, said he was going to die, and was unable to swallow anything. Soon after 6 A.M. he had the first real spasm, which alarmed his parents; he tried to jump out of bed whilst in it. His father came for me, and on hearing his account I suspected the nature of the illness and went at once. On arriving about 7 A.M. I found the boy in great distress, with wild staring eyes, foaming at the mouth, constantly spitting, and the muscles of the neck rigid. I gave him a teaspoonful of a strong

solution of chloral hydrate, most of which he got down, and it at once brought on spasm of the muscle of the pharynx and larynx, also of the thoracic muscles; the eyes were almost protruding; there were lividity of the face and difficulty of breathing. Two men had the greatest difficulty to prevent him from springing out of bed. He complained of a strange sensation in the right arm; the fingers of the right hand were rigid, and he wanted some one to hold the hand. He was quite sensible and talkative, said he was going to die, and soon afterwards expressed a wish to see his clergyman, who came. On seeing the serious nature of the case I recommended the patient's immediate removal to the hospital at Wakefield, sent for a cab, and along with his father took him there. Soon after my arrival, and before removing him, he became much calmer and had no more convulsions until after his arrival at the hospital. On the way to the hospital the muscles of the neck were rigid and viscid, and frothy mucus was constantly working out of the mouth. He talked all the way sensibly, but seemed now afraid of our doing anything for him, such as covering him up in the blankets, and would do it for himself. He continued in this state until after arriving at the hospital, a journey of three miles, when he was at once put to bed. The convulsions now came on rapidly. The surgeon (Mr. Walker) and the house surgeons quite agreed with me as to the nature of the case. A strong hypodermic injection of morphia and strychnia was given, also chloral by the rectum. This kept him quiet for about an hour, and he slept. This I was told by the house surgeon. After an hour the spasms came on more frequently, and he died in one about 4 P.M. the same day, nothing appearing to have any effect upon them. He was conscious to the last.

Horbury, Wakefield.

DEGREES OF KNEE-JERK.

By LEONARD J. KIDD, M.D. BRUX.

FOR the last two years or more I have been in the habit of recording the degrees of the knee-jerks by means of a scheme which was suggested to me in the following way:—I had often seen physicians mark a particular jerk as + or ++ with the purpose of conveying the meaning of exaggerated and greatly exaggerated respectively. These signs brought to my remembrance the well-known "Degrees of Intra-ocular Tension" of the late Sir W. Bowman. I thought one might frame a scheme of various degrees of knee-jerk by means of *plus* and *minus* symbols. It was clear to me that to be of any value, apart from that of saving time in clinical work, these signs must convey a definite meaning, so that any particular *plus* or *minus* jerk could be at once put into a certain category. I found that there were three distinct groups of excess of jerks and three of diminution, the last being the absent jerk if I may speak of a diminished jerk as being an absent jerk. These, together with the normal degree, make up seven degrees; for those who wish to follow literally the analogy of Bowman's notation an additional *plus* query and *minus* query can be added, but I think these are not needed.

After very many attempts the best classification I can suggest is as follows:—

K.J.n. = normal jerk—i.e., of normal quickness and of normal excursion of the leg and foot. Right jerk written as R.K.J.n.; left jerk as L.K.J.n.

K.J. + 1 = distinctly increased quickness and excursion, but not obtained by a blow above the patella. K.J. + 2 = still more lively and extensive, and obtained by supra-patellar blow. K.J. + 3 = as in K.J. + 2, but with addition of clonus of anterior thigh muscles; this is usually found, I think, only in cases where foot-clonus is also obtained.

K.J. - 1 = distinctly diminished quickness and excursion, but obtained without reinforcement—e.g., by Jendrassik's method. K.J. - 2 = still more sluggish, and obtained only with reinforcement. K.J. - 3 or 0 = absent, even on reinforcement and after many careful trials by all known methods.

I occasionally find that both jerks come within the same category, but one is more marked than in the other. This I have seen mostly in that very common class styled K.J. + 2. In such cases, if one jerk is about half way, as to quickness and excursion, between + 2 and + 3, but the other very nearly as quick as + 3 usually is, I call one + 2½ and the other + 2½. By this means a still more accurate result is obtained than by simply calling both + 2. The same can be

done, if necessary, with the *minus* degrees. I have recently seen a case of great obscurity (to me and to three other medical men who previously saw the patient) where I have marked: L.K.J. + 2½; R.K.J. + 2½. In this case there is in the left foot only a condition of spurious ankle-clonus. Even with the patient's boots off I have been unable to obtain true and decided clonus in the left foot. Now, the point of paramount importance in this case is to know whether this is one of organic disease. Should the L.K.J. advance to + 3 I shall consider it is almost certainly so. It is, I believe, generally considered by the best authorities that K.J. + 3 means organic disease in ordinary clinical work. Possibly it would be found in many cases of very marked supervenosity of the blood. It was obtained in Dr. Risien Russell's experiments on rabbits artificially asphyxiated¹ about two and a half minutes after the trachea was clamped. I think that K.J. - 2, and possibly K.J. - 1, may sometimes point to the approach of tabes or other diseases characterised by absent jerks in their fully developed stages. But in these two *minus* degrees we have to bear in mind the element of muscular rigidity on the part of the patient; stoutly built people frequently, and children sometimes, present jerks of sluggish response and difficult to obtain at the first stroke. Personally, I attach no diagnostic importance to the not uncommon flinching on the part of patients (these are generally, according to my experience, in that common class K.J. + 2), or to the patient's sensation of the jerk up the thighs and back. Some physicians, however, hold that these features point to "functional" disease as against organic; but I have seen them in cases of undoubted organic disease, and they are, of course, often absent in the functional cases. A jerk which comes into the class K.J. + 2, but which is obtained by a mere flick of the finger-nail, we should usually call + 2½. I think, as it shows very great myotatic irritability. I have used the above scheme myself for quite two years with considerable saving of time; anyone will see, I think, that any jerk can be easily, quickly, and without hesitation placed in one of these seven degrees. In testing the jerk I always now, after finding it present, strike the quadriceps just above the upper border of the patella. In this way I at once discover whether the case is one of great irritability of jerk; this applies especially to cases presenting merely an increased jerk. I use the ulnar border of the hand first, then a weighted stethoscope, then a tap with the two fingers as in percussion of the chest, and lastly a flick with the finger-nail. By these means I think we best estimate how far the jerk approximates in quickness and excursion to K.J. + 3. Doubtless some, and perhaps many, cases of K.J. + 1, + 2, - 1, and - 2 are cases of organic disease in either early or later stages, but about + 3 and 0 there will, I fancy, be little doubt. I believe that those who give this scheme a trial will soon find it a help, and the initial difficulty of acquiring any new formula is soon overcome by an accurate observer endowed with the invaluable faculty of attention. Should it be widely adopted, the poor over-burdened medical student may find comfort in the thought that we acquire knowledge more readily in the golden time of youth than in the "years that bring the philosophic mind." The ideal method of measuring the knee-jerks appears to me to consist in the use of an instrument, yet to be invented, somewhat on the lines of Mr. Priestley Smith's tonometer, that shall record: (1) the force of the blow which elicits the jerk, (2) the quickness of motor response, and (3) the extent of the excursion of the leg and foot. I have hitherto failed to devise a scheme for recording varying degrees of the other jerks, such as the wrist, triceps, and the jaw-jerk.

George-street, Hanover-square, W.

¹ Quoted by Dr. Hughlings Jackson in his *Neurological Fragments*, No. 5, in *THE LANCET* of Jan. 20th, 1894.

THE SUPPLY OF ANTITOXIN IN ORMSKIRK.

The Ormskirk Rural District Council at its last meeting resolved to supply diphtheria antitoxin serum and sterilised apparatus to all registered medical practitioners for use within the district free of charge. Arrangements have also been made for the bacteriological examination of samples of doubtful throat exudation, and Mr. Herbert Peck, the medical officer of health, has caused these unwonted facilities to be notified to the members of the profession in his district. It is gratifying to find a public administrative body so promptly taking such liberal and enlightened views of its functions.

THE MECHANICO-GYMNASTIC AND BALNEO-THERAPEUTIC TREATMENT OF CHRONIC CARDIAC DISORDERS.

By DR. GROEDEL.

THE physical treatment of chronic diseases of the heart has only recently assumed an important place in therapeutics. I therefore wish briefly to state my views of the general treatment of these diseases, based upon an unusually extensive practice of twenty years in Nauehm, and I shall describe what may be called the speciality of Nauehm—i.e., the balneo-therapeutic treatment, adding a few words about the gymnastic treatment and the so-called "Terrainkur" (walking uphill, &c.).

Although formerly treatment by baths was considered as essentially contraindicated for patients suffering from heart disease, a contrary opinion has been expressed by Professor Beneke¹ as early as the year 1859 in his first work on Nauehm, and still more forcibly in his second work, which appeared in 1861. Among those patients suffering from rheumatism who came under his treatment in Nauehm there were eight cases of organic heart disease, and he found that taking the warm brine baths was not only beneficial to their rheumatism, but to a certain degree also to the cardiac trouble. In 1870 Beneke wrote a larger work,² in which he explained his views more fully, and it was only after this that patients with heart disease, more especially in conjunction with rheumatism, came to Nauehm in great numbers. In a monograph³ which appeared in 1872 he recorded 101 cases, and he gave a detailed account of 55 of them. In 1875 he published another paper on the same subject in the *Berliner Klinische Wochenschrift*. In these works Beneke draws attention to four main points in the treatment of heart disease at Nauehm—viz., firstly, the removal of rheumatic tendencies whereby relapses of acute rheumatism, which would increase an existing cardiac lesion, are prevented; secondly, the effect of these baths being to promote absorption, he believes that, as they cure other effects of rheumatic inflammation, so they will also be beneficial to the cardiac valvular apparatus; thirdly, he found that the baths always had a soothing effect upon the heart's action even where there was no rheumatism; and consequently, fourthly, he very often found in old valvular disease a striking improvement in compensation, as well as in the general state of health, in cases where no other treatment had been of any service. He has thus the indisputable merit of having introduced a new kind of treatment into the therapeutics of chronic heart disease. A paper written by me⁴ described a very marked case and showed how, under certain circumstances, the thermal brine baths containing carbonic acid had the same effect as digitalis on heart diseases. This was the first announcement that the baths "increase the energy of the heart's action." It was followed by other papers⁵ which partly brought to light new facts concerning the effect of the baths of Nauehm upon the circulation of the blood, and partly confirmed by many observations what was already known. Thus the assertions made by Beneke that the baths always lessened the frequency of the pulse, and that the decrease lasted for some time after the baths had been taken, were proved to be correct. It was further observed that the blood pressure was increased as well as the power of respiration. From the beginning it was evident that to exclude any form of cardiac disease entirely was impossible, and although Beneke, as well as myself, formerly believed that arterio-sclerosis must be excluded from the treatment for theoretical reasons (increase of blood pressure), yet I can now state that the baths are beneficial in these cases also, for in the course of years I have treated in this

¹ From 1852 to his death in 1883 he was physician at Nauehm, and since 1856 he at the same time occupied the chair of Professor of General Pathology and Pathological Anatomy at the neighbouring University of Marburg.

Schott: Die Wirkung der Bäder auf's Herz; Berliner Klinische Wochenschrift, 1880, No. 25. Groedel: Zur Behandlung Herzkranker; Berliner Klinische Wochenschrift, 1883, No. 25, &c.

way many patients suffering from advanced arterio-sclerosis without in one single instance having found any unpleasant result; on the contrary, the usual effect was a considerable improvement of the circulation and general state of health. Even for aortic aneurysm I can say the same thing, and in a lecture delivered at the Balneologists' Congress in Berlin¹ I described such a case combined with tachycardia paroxysmalis which was greatly benefited after several courses of the baths. Of course such patients are treated differently to those affected only with a nervous cardiac malady, or with a simple disorder of the cardiac valves.

The carbonic acid thermal brine baths tend to soothe and regulate the heart's action and to strengthen the cardiac muscle. A strictly physiological explanation of this effect is not possible, as it is, indeed, difficult to give a perfectly non-hypothetical explanation of the effect of any other bath treatment. It is supposed that, by stimulating the peripheral circulation, a certain influence on the cardiac action is obtained, and that at the beginning of the bath and as long as the impulse of the cold lasts an increase of the intra-cardiac pressure is procured by the contraction of the cutaneous vessels, with an incentive to increased activity of the cardiac muscle. This is soon followed by relief of the internal organs, especially the heart, owing to the dilatation of the cutaneous vessels caused by the carbonic acid, in spite of the cool temperature of the bath. If the contraction of the cutaneous vessels lasts too long, as is the case with the ordinary cold baths, an over-exertion of the heart would take place. The baths are at first prescribed with a temperature little lower than the normal heat of the body, and with such a small quantity of carbonic acid that it can only have a very slight effect on the heart and vessels. If the irritation of the cold has too great an effect, lasts too long, or is not counter-balanced by the carbonic acid (as shown by cyanosis, shortness of breath, or continued shivering), then the temperature of the bath must be raised and the amount of carbonic acid increased afterwards. When the patient can bear the carbonic acid well the temperature is again cautiously lowered. To obtain better nutrition and action of the cardiac muscle it is necessary to stimulate the heart to more powerful action, not continuously, but so as to alternate rest with exercise in a manner suitable to each individual case. As has been seen from the above explanations, the baths answer this purpose perfectly, and therefore it is not necessary to give fuller particulars as to how the cardiac muscle is at length revived and invigorated by the effects of a continued course of them. These different factors combine to produce the favourable result which is so often to be seen in the Nauheim treatment, and therefore the baths are adapted to all kinds of cardiac mischief that require an increase of the cardiac action; it is quite immaterial whether the illness arises from valvular defects or is the result of a diseased cardiac muscle or of atheromatous degeneration of the vessels, or even of generally abnormal nourishment, such as obesity. Great success has also been obtained in conditions which result from irregular innervation of the heart, especially in neurasthenia cordis.

I will now give a short description of the method of treatment. I begin with baths containing only a slight quantity of carbonic acid and salt, having a temperature of from 90° to 92° F., and lasting from five to ten minutes, according to the reaction produced; as time goes on the carbonic acid and salt are increased and the temperature is reduced (sometimes as low as 83° and even lower), the time being increased to fifteen or twenty minutes. At the beginning there is a pause every third or fourth day, but later at longer intervals. I often make the patients begin with weak baths, especially in cases of angina pectoris and aortic aneurysm. They must be warned against taking chill after the bath, as that would produce a contraction of the cutaneous vessels with shivering and oppression of the heart. Most of the patients are ordered from one to two hours' repose in bed after the bath, and it is only in some exceptional cases that I make them take a walk for from a quarter of an hour to half an hour before resting. In prescribing the bath treatment it must always be kept well in mind that a proper proportion of rest and exercise must be given to the heart, and, although at the beginning the former predominates, yet later the latter plays the chief part in the treatment.

Artificial thermal brine baths containing carbonic acid can be prepared in several ways. The proportion of salts contained in the Nauheim springs, which varies in

amount from 1 to 4 per cent., often being made still stronger with mother-lye, can be replaced by a corresponding quantity of kitchen salt and Nauheim spring salt or mother-lye. Carbonic acid can be produced in several ways, as with bicarbonate of sodium and muriatic acid, or with bicarbonate of sodium and bisulphate of sodium, &c. The carbonic acid in these baths escapes very quickly; those artificial baths made on the Lippert system are preferable, because in them the carbonic acid is better absorbed; yet even they are far from being so effective as the natural Nauheim bath, from which they differ considerably in many respects. The effervescent flowing baths, "Sprudelstrombäder," a peculiarity of Nauheim, in which the brine, unusually rich in carbonic acid, flows continually through the bath, have a powerfully stimulating effect on the general nervous system, which must operate as a tonic on all the nervous organs, including the innervation of the heart, in a much milder manner, though certainly not less powerfully than the cold water baths. Artificial carbonic acid baths, which were first recommended by Nauheim physicians, have yielded good results, but at Nauheim the natural baths can be graduated most exactly, and the bathing treatment—which was formerly limited to weak carbonic acid baths, and then only applied to a certain number of those patients suffering from heart diseases—has now been brought to such a state of perfection and exactness as is to be found in no other place. Besides those illnesses which are amenable to simple brine baths (scrofula, diseases of women, &c.), the carbonic acid thermal brine baths are especially indicated for affections of the peripheral and central nervous system, gout, and the different forms of rheumatism.

I now come to the other modes of treatment generally in use for disordered circulation in addition to the bath treatment. There can be no doubt that the effect of the baths in a watering place is in a great measure influenced by the continued stay in pure strengthening air and the avoidance of all excitement; it is also quite certain that in such places the patients are a great deal readier to follow the injunctions of the physician as to their whole manner of living, and more especially his directions for their diet, than they are at their homes. Particular attention is paid to dietetics in Nauheim. I am always when prescribing diet led by the special circumstances of each individual case, both as regards the choice of food and the use of alcoholic stimulants &c. It is well known that Oertel recommended a restricted use of fluids in cases of disordered circulation, whether due to obesity or any other cause; but shortly after the publication of Oertel's book I gave it as my opinion in a lecture² that this principle should not be carried too far.

It will not be out of place to give here a short account of the so-called "Terrainkur" (walking uphill &c.), which is recommended in the above-mentioned book of Oertel. But I must first refer to the use of gymnastics as an auxiliary means in the bath treatment at Nauheim. For many years gymnastics have been employed by physicians in Sweden for all circulatory disorders, and were eventually introduced into Nauheim. Gymnastics are divided, as is well known, into "active," "passive," and "resisting" gymnastics. It is the last of these that plays the principal part in the treatment of heart diseases. The gymnastic exercise is performed either by means of machines, or manually by persons especially trained for this purpose. The principle and aim of exercises are to stimulate the circulation in the muscles brought into action, whereby the cardiac muscle is reflexly induced to stronger and more abundant contractions, with a simultaneous relieving of the venous, and acceleration of the arterial, portion of the circulation. At first I only allow patients to exercise the upper extremities, and then proceed to some movements of the lower extremities and trunk, where all such movements are to be avoided as prevent free motion of the diaphragm or the wall of the thorax. Especial care should be taken that the patient does not make jerky movements, but slow and continuous ones, at the same time neither holding nor increasing the breathing. The exercise should not be made on a full stomach, and there should be frequent pauses to let the heart, which becomes somewhat agitated, calm down again. Whereas formerly manual gymnastics only were in use in Nauheim, we are now able to employ mechanical exercise, and from the experience that I have had I decidedly prefer

¹ Ueber nervöse Herzklopfen und sonstige auf Innervationsstörungen beruhende Herzaffecten; Berliner Klinische Wochenschrift and Deutsche Medicinalzeitung, 1890.

² Erfahrungen bei der Behandlung von Circulationsstörungen nach Oertel'scher Methode. Congress of Balneologists at Berlin, 1888.

the mechanical gymnastics to the manual. Still, there are some cases for which manual gymnastics are to be preferred, especially for persons who may only do little exercise at a time, several times daily, and with a limited amount of movements. That both kinds of gymnastics should be performed under careful medical superintendence is a matter of course.

The success of the "Terrainkur" is based mainly on the same principles as that of the gymnastics; yet there are also other factors that go to explain the beneficial effect, among which I attribute the greatest importance to its influence on respiration, and so I frequently prescribe pulmonary gymnastics alone as having a very advantageous effect on heart disease. Hill climbing, which was made known to us as a remedy by Stokes, and which under certain circumstances may strengthen a weak heart, was frequently prescribed by me before the publication of Oertel's work, though certainly more often after Oertel had explained the matter more methodically. I have, however, pointed out in the above-mentioned lecture the danger of generalising this method, and what I said at that time (1886) is now universally acknowledged—namely, that Oertel's "out-door exercise" or climbing treatment could only be recommended in cases of diminished cardiac power resulting from general obesity, of insufficiency of the cardiac muscle in patients with anæmia and a general flaccidity of the muscle, or of kyphosis and kyphoscoliosis, causing disordered pulmonary circulation; but it can only be used in few cases of cardiac valve lesion, more especially if it be mitral insufficiency, when the disordered compensation is still in its first stages or when, by previous courses of bathing, an almost sufficient compensation has been attained. Therefore hill climbing is suited to only a small portion of those patients with disordered circulation who come to Nauheim for treatment. Gymnastics are generally to be preferred to Oertel's "Terrainkur" because they do not exert the heart so much, can be regulated better, and are often admissible in cases in which the "Terrainkur" would be absolutely impossible. I have here referred more particularly to walking uphill, for walking on level roads can be borne by every patient with heart disease if it is done at a slow pace, with frequent rests and regular breathing, with the avoidance of all talking during the walk, and if every now and then a deep breath be taken. Of course, the length of the walk must be regulated by the patient's power of endurance. Yet there are always among the patients sent to Nauheim a number for whom the only treatment at the beginning that can eventually lead to a good result consists in absolute rest and repose, avoidance of every kind of bodily exertion, and the use of the bath-chair.

I have still to mention massage, which—usually applied in the form of a general massage—has likewise the effect of removing venous stagnation and stimulating the action of the heart by increasing the circulation in the skin and peripheral muscles. It is often used as an aid to the bath treatment in conjunction with gymnastics, and often also as a substitute for the latter in those not too rare cases in which gymnastics cannot be borne, such as arterio-sclerosis, most cases of aortic insufficiency, or advanced fatty degeneration of the cardiac muscle, &c.

I should not omit to state that in many cases medicinal treatment is not quite inadvisable, but I must also add that I could quote many instances in which all the drugs tried at home had produced no result, whereas the same remedies in connexion with a course of baths had acted in a most striking manner. Yet this does not affect what I have said elsewhere about the contraindications for Nauheim—namely, that it is not advisable to send patients here for a course of the baths on whom medicaments, and especially digitalis, produce no reaction whatever. As regards the success which one may hope to obtain from the treatment we are in some cases very glad to have obtained a temporary improvement, even if it only lasts for a few months; yet by far the greater number of our patients, and especially those who repeat the course of baths regularly, succeed in establishing a relatively good state of health lasting over a number of years.

Nauheim, Germany.

A CASE OF ACUTE PERIOSTITIS FOLLOWED BY RAPID PYÆMIA AND DEATH.

By ERNEST W. G. MASTERMAN, F.R.C.S. ENG.,
ASSISTANT MEDICAL OFFICER, ENGLISH MISSION HOSPITAL, JERUSALEM.

On Feb. 13th, 1895, I was called to see a little Jewess, aged eleven years, who had just had a rigor accompanied by high fever, headache, and nausea. There was no history of any fall or any complaint of pain in any of the limbs. It seemed like an ordinary case of ague—which is the commonest fever here—and was so treated. On Feb. 14th I saw the child again. She still had fever with frequent vomiting, and all along the front of the right leg there was a patch of diffuse redness. There was no fluctuation. Unfortunately, I thought it was a case of commencing erysipelas, which is very common here, while acute periostitis is exceedingly rare. This was the more regrettable inasmuch as I was not called to the case again for a week. On Feb. 22nd the patient was admitted to the English Hospital, Jerusalem, and again came under my care. The history during the interval was that on the 15th the patient had been attacked with pain in all her joints. The pain was so severe that the right leg was thought by the mother to be "all right," and the disease to be rheumatism. The child at this time looked very ill and was very anæmic, the lips looking quite white. The temperature was over 103° F., and there was no shivering and no sweating. All the joints were very tender and were held constantly still; the wrists and elbows were especially painful. The right leg was swollen, but all the redness had disappeared. There was distinct fluctuation over the inner surface of the tibia from the internal malleolus for about four inches up the leg. The skin over this area was white and not tense. The patient being put under chloroform, an incision was made and three or four drachms of thick blood-stained pus were evacuated. On introducing the finger about two inches of the shaft of the tibia—on its inner and posterior part—were felt to be bare. Two additional incisions were made for more complete drainage and tubes were inserted. The temperature that evening rose to 104·6°. The bowels were open four times with liquid, but not markedly fetid, stools. She scarcely slept at all that night, was very restless, and in much pain both in the leg and in her joints. From the 23rd to the 26th she continued to have a high temperature, the evening temperature being always two or three degrees above that of the morning. The leg discharged freely. All the joints continued tender, but especially the right wrist and left elbow. These joints were swollen slightly, but not reddened. The child cried out with pain constantly and slept badly. She was made to take a good deal of nourishment in the form of milk and eggs, and stimulant in the form of an ounce and a half of brandy and half an ounce of meat essence daily. She was given quinine and opium and at night sulphonal. On the 26th the two most painful joints were put on splints. She took food better. The tongue became more moist and her general condition seemed to be improved. At 5 P.M., however, she had a rigor lasting five minutes and the temperature rose to 104·8°. She sweated all night after and complained of great pain, especially in the head. The motions were very light in colour, thick, and very foul. There was no vomiting. During the 27th and 28th there were no more rigors. She constantly perspired and was very restless. The bowels were open frequently. On the night of the 27th the breath was noticed to be very foul. A small abscess formed just below the angle of the right scapula and was opened on the 28th, about one drachm of thick white pus being evacuated. She continued to take food fairly well. Her evening temperature was always above 104°. On March 1st the morning temperature was 103°. She had no more rigors, but the profuse perspiration continued. She could not lift her arms at all, but her joints were not externally worse. She was semi-conscious all the latter part of the day. The temperature at 6 P.M. was 104°, and at 10 P.M. 105·4°. She continued semi-conscious and died at 7 A.M. on March 2nd. No post-mortem was allowed. I have thought this case worth recording in spite of its most unsuccessful issue. Firstly, because it exhibits in a marked degree the difficulties attending the diagnosis of cases of acute periostitis; and, secondly, because of the exceedingly rapid onset of the symptoms of

FOOTBALL CASUALTIES. — On the 13th inst., during a match at Flint, a member of the Flint team fractured his femur, and a player in the Holywell team "dislocated his knee-joint."—On Saturday last, in the course of a match between the Bradford and Bowling Old Lane teams, a player "displaced one of his ribs."

general pyæmia. On the third day after the initial rigor there were symptoms of pyæmia in the form of pain in all the joints, which pain became so severe as for a time to cause the condition of the leg to be almost forgotten. Then, thirdly, it is interesting to notice that though the blood-poisoning was severe enough to cause death on the seventeenth day from the initial rigor, yet the amount of bone affected was quite small. Probably, had the patient lived, the sequestrum, which would subsequently have had to be removed, would have been only about a couple of inches long and one inch broad, and possibly less. It would seem that the poison was in a sufficiently large dose to kill before it could do much damage locally. In notes of a good many cases which I took at St. Bartholomew's Hospital I find that on an average the patients whom I saw there were admitted between two or three weeks after the onset of the disease, many being previously treated for other diseases outside. In these cases, too, there is frequently a large abscess and great destruction of bone. Pyæmia frequently, too, sets in during prolonged suppuration after the original abscess has been opened; but that form of pyæmia is more chronic, and, as far as I can judge, less fatal, especially if amputation is resorted to early enough. In my case I do not believe amputation would have been any good when the child came under my care in the hospital, as the whole system was already so greatly affected.

ACUTE DELIRIOUS MANIA FOLLOWING ACUTE DRY PLEURISY IN A GIRL TWELVE YEARS OF AGE.

By W. R. BATES, L.R.C.P., L.R.C.S. IREL.

IN the course of nearly twenty years' experience I have never met with a case similar to this, which emboldens me to bring it before the readers of THE LANCET. An intelligent and well-nourished girl twelve years of age, gasser in a silk spinning mill, first seen on Sunday, Oct. 28th, 1894, had not been well from the previous Thursday, complaining of headache, pains in the limbs, and general lassitude, but had worked up to the previous morning, when she had to come out of the mill. She was suffering from pain in the right side of the chest, which increased on inspiration and by pressure over the lower ribs. The respirations were hurried and shallow, with slight cough, but no expectoration. The tongue was furred and moist; the bowels acted regularly. There was no vomiting. The patient said also that her head ached very badly. The temperature in the axilla was 103.4° F., and the pulse 112. There was no dulness on percussing the chest, but on auscultation there was a friction sound heard over the right base anteriorly; the heart sounds were normal. A diaphoretic mixture of acetate of ammonia with potassium bicarbonate was ordered, with hot linseed-meal poultices, mixed with one-twelfth part of mustard, applied to the right side; the diet was to consist of milk with a little soup. Next morning the temperature had fallen to 100°, the respirations were less hurried, but there was still the quick pulse and there had been very little sleep. On the 30th the temperature was normal. The respiration was regular, but the pulse-rate still kept high (120), and she had had another sleepless night. She was taking food well and seemed to be convalescing rapidly. On the 31st her sister came for me before breakfast, asking me to see my patient at once, as she had not slept and was very excitable, saying there was a woman behind the door with something over her face continually looking at her, and that cats, dogs, and other animals were running all over the bed and biting her legs and toes. When seen she was not at all violent, but it was with difficulty she could be persuaded to lie down. She talked quite rationally, however, until questioned about the woman, when she became very excited, reiterating the statements already made to me. Her temperature was normal, but the pulse-rate was quick. A mixture of potassium bromide with vinum antimoniale was given every three hours. The room was ordered to be darkened and the child kept perfectly quiet. I was away all day, and on arriving home at night

found I had been sent for several times. On entering the room I found it required the united efforts of several women to keep the girl in bed. She was violently delirious, but her chief delusion was that she was floating down the river in a tent with the water gradually filling it, and that we should all be drowned. She recognised me, however, and asked me to take her away to a safe place. With a little coaxing I persuaded her to lie down, and took her temperature in the axilla; it was still normal. A draught containing two scruples each of bromide of potassium and chloral hydrate was ordered, half to be given immediately and the other half in two hours if required. She fell asleep for a little while after the first half, and then had the second portion administered, when she slept for about eight hours. Waking up quiet and free from delirium, but still full of delusions, she slept well the following night without a sedative, and gradually regained her usual health, but it was rather more than a week before the delusions entirely disappeared. I think, on looking at her and the family history, we have a clue to the cause of the mental disturbance, following what was only a mild attack of pleurisy. In infancy and childhood I attended her, when she had several convulsive attacks during the period of dentition and from gastric disturbance, showing that she has a tendency to have her nervous system easily thrown off its balance; I also attended two of her sisters, who died from tuberculous meningitis. Her mother died from lardaceous disease following spinal caries. The girl is now in good health, mentally and bodily, has got stout, and is following her usual employment.

Addingham, Yorks.

A MODIFICATION OF PHELPS'S OPERATION FOR THE RELIEF OF TALIPES EQUINO-VARUS.

By T. H. KELLOCK, F.R.C.S. ENG.,

MEDICAL SUPERINTENDENT, THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

THIS operation having now been performed for some years, we are able, to a very fair extent, to form an opinion as to the ultimate benefit derived from it, and many surgeons must have been somewhat disappointed at the tendency to relapse which takes place some time after the abandonment of the splints or other supports which have been used to keep the foot in the corrected position, the part of the foot in front of the wound becoming slightly adducted and the sole inverted. This appears to be particularly the case in those instances where the large open wound resulting from the operation has been allowed to granulate and close by itself; it is obviated, to a certain extent, by planting epithelial grafts taken from some other part of the body on to the raw surface at the time of, or soon after, the operation; but in cases treated in this way the resulting scar is unsightly, and there remains a deep sulcus formed by the drawing together of the sides of the wound thus covered by epithelium. It occurred to me that this might be further remedied by making use of some of the redundant skin which is always present on the outer side of the foot when this has been brought into the straight position, and by the kindness of Mr. J. H. Morgan I was able to perform the following operation on a case under his care. The patient was a healthy-looking girl six years of age, the subject of bad congenital talipes equino-varus—an essentially favourable case for the performance of this operation. Continual walking on the outer side of the foot had caused the usual thickening of the skin in that position, which had to be softened by being treated with a wet dressing a day or two before the operation, which was performed in April last. After dividing the tendo Achillis subcutaneously and completing the operation as described by Phelps, with division of the tendons of the tibialis anticus, tibialis posticus, and flexor longus digitorum muscles, the foot could be brought into a very good position; a flap of the whole thickness of the skin, about an inch wide, was then cut on the outer side of the foot by two parallel incisions reaching from the upper end of the operation wound to the sole, and dissected off the underlying structures, the skin being brought together underneath it by sutures. Five or six days later, the flap appearing to be thoroughly well nourished, the lower end was divided and, leaving the upper end still attached, was turned across and secured by one or two horsehair stitches into the deep wound on the inner side of the foot, which was by this time mostly

covered with granulation tissue, and the foot and leg fixed in plaster of Paris. The healing of both wounds was quickly accomplished and the plaster-of-Paris splint dispensed with about three months after the operation. Some time afterwards, as there was still a tendency to equinus, the tendo Achillis was again divided and the foot put into plaster-of-Paris for a fortnight. The result now—ten months after the operation—is very satisfactory, the foot being in good position, with more strength in it than one dared hope for after the division of the tendons of so many important muscles.

Great Ormond-street, W.C.

CASE OF FRACTURE OF THE BASE OF THE SKULL, WITH OUTWARD DISPLACEMENT OF BONE.

By C. B. DALE, M.R.C.S. ENG., L.R.C.P. LOND.,

LATE HOUSE SURGEON, DUCKINGHAMSHIRE GENERAL
INFIRMARY, AYLESBURY.

ELEVATED fractures of the vertex of the skull are described as the result of oblique cuts. In the following case a similar condition affected the base. On Sept. 26th, 1894, a man aged fifty-one years was working on the Great Northern Railway line when an iron plate measuring 13 in. \times 7½ in. \times ½ in. flew off the engine of a passing express and struck him behind the left ear. When seen a few minutes afterwards he was in a semiconscious condition, but rapidly became comatose. There was an irregular, lacerated wound about 5 in. in length, extending downwards and forwards behind the left ear as far as the angle of the jaw. The skull was perforated just behind the mastoid process, and a circular piece of bone about 2 in. in diameter was cut out and turned back in the posterior flap. There were some loose splinters of bone lying in the wound, but the edges of the opening in the skull were not depressed, and no fissures could be detected extending from it. The surface of the brain was lacerated. The wound was washed out with carbolic acid lotion and brought together with carbolised silk sutures, the piece of bone being replaced and kept in position by the flap to which it was attached. The patient made a good recovery. The wound healed by first intention, with the exception of the lower angle, from which a small quantity of cerebro-spinal fluid continued to escape for some days. Four days after the accident he developed left-sided facial paralysis, but this has since almost completely disappeared. He is now back at work and complains only of slight weakness of the right leg.

KING'S COLLEGE HOSPITAL.

A CASE OF FLOATING KIDNEY WITH INTERMITTENT HYDRO- NEPHROSIS CURED BY FIXING THE KIDNEY IN THE LOIN.

(Under the care of Mr. WATSON CHEYNE.)

THIS case illustrates a condition of the kidney which is much more common than was supposed a few years ago; in fact, the relationship between movable kidney and hydro-nephrosis was not mentioned in our text-books and was perhaps not recognised. Probably the most interesting and important contribution to this subject (intermittent hydro-nephrosis) is that by Terrier and Baudouin,¹ who collected a series of eighty-three cases. They found that the most

common cause of this condition is a movable kidney, which when displaced causes a kink in the ureter, the escape of urine being thus prevented until the kidney has returned to its normal position. They state that such a condition usually becomes a permanent one, because in consequence of inflammatory changes about the kidney adhesions form which hold it in its displaced position. The symptoms produced by intermittent hydro-nephrosis were well shown in the case which follows, whilst the treatment carried out has proved very successful. It is, of course, advisable that the operation should be performed as early as possible, so that the inflammatory changes which are only too apt to ensue and produce destruction of kidney substance, and may possibly necessitate the operation of nephrectomy, may be prevented.

A widow aged thirty-five years was admitted to King's College Hospital on Nov. 16th, 1893. Four years before admission she first began to suffer from attacks of pain in the left side. These attacks lasted from two or three days to a fortnight, and from that time she had had attacks of this kind every week or ten days. At first she noticed that the attacks occurred especially after exertion, such as lifting heavy weights, and relief was sometimes speedily obtained if she lay down on her side. Latterly, however, the attacks had occurred without exertion, and even on turning in bed. The pain was of an aching character, beginning mildly at first, gradually increasing in severity, and subsiding either gradually or sometimes pretty quickly. For the last year, coincidently with each attack of pain she had noticed the appearance of a lump in front and above the left anterior iliac spine, which was very tender and was the seat of the pain. It appeared and disappeared coincidently with the pain. Tenderness remained for some days after the attack. During these attacks she did not notice any frequency of micturition or alteration in the quantity of urine passed, nor had she noticed any increase in the quantity of urine when the tumour disappeared. She had, however, frequently noticed blood in her urine, both during and in the intervals between the attacks. She was admitted to hospital during an attack, but on her being examined two days later the pain and tumour were found to have completely disappeared. An elongated mass which seemed to be the remains of the kidney was, however, felt and was freely movable. The patient's general health was good. The urine was acid, of sp. gr. 1030, and with a considerable deposit of urates, but no albumen, sugar, or blood. As no lump was present she went to the ophthalmic wards on account of a keratitis from which she had suffered for some months. She afterwards went out for a few days and returned on Dec. 20th with a fresh attack of pain in the lumbar region. On examination a large, soft, rounded swelling about the size of two fists was felt in the left lumbar region, extending as low as the anterior iliac spine and passing up under the ribs. There was also bulging in the left lumbar region behind. There was dulness over this area, and the swelling was very tender to the touch. On considering the history and symptoms Mr. Watson Cheyne came to the conclusion that this was one of the cases which have been recently described by Mr. Clement Lucas, where hydro-nephrosis had followed on a movable kidney, and that the attacks of pain &c. coincided with a kinking of the ureter from an alteration in the position of the kidney. As it was evident that considerable kidney substance still remained, Mr. Watson Cheyne decided to wait till the attack passed off—that is to say, till the position of the kidney which led to kinking of the ureter had given place to a position in which the ureter was free—and then to try to fix the kidney in that position. The swelling and other symptoms had completely disappeared by Jan. 12th, 1894, and accordingly on Jan. 17th the usual oblique posterior incision was made and the kidney exposed. Considerable remains of kidney substance were found, of a horse-shoe shape, and in front and below a large empty sac, the dilated pelvis. The kidney having been placed as nearly as possible in its normal position, a portion of the capsule was stripped off and stitched in with stitches which united the divided layers of muscles somewhat after the manner described by Mr. Arbuthnot Lane. There is nothing special to note about the after-progress of the case except that two of the superficial stitches found their way out through an angle of the wound left open for drainage. The patient left the hospital on Feb. 24th, not having had any further accumulation or attack of pain. She was seen quite lately, when she stated that she had remained perfectly well and free

¹ *Revue de Chirurgie*, Paris, 1891, vol. ii. *Sajous' Annual of the Universal Medical Sciences*, vol. iii., B. 23.

from attacks for months; indeed, she had only had one very slight attack a few days after leaving the hospital, which, however, subsided in a few hours and was not accompanied by any appearance of tumour. As more than a year has now elapsed since the operation she may be regarded as well.

HOSPITAL FOR WOMEN AND CHILDREN, LEEDS.

A CASE OF OSTEOMALACIA; REMARKS.¹

(Under the care of Dr. J. B. HELLIER.)

THE disease of which the following is a good example is fortunately rare in England, and the remarks which are appended to the case by Dr. Hellier give a good summary of most of our present knowledge on the subject. Winogradsky² described a micro-organism which he had found in the blood of a patient suffering from osteomalacia and which he considered might be the cause of the disease; others have failed to confirm his observations, and the cause remains unproved. Petrone, who also considers that the cause may be a micro-organism, states that it may be destroyed by the use of chloroform, and Latsko succeeded in curing a patient by chloroform narcosis. Phosphorus has been used with considerable success by Steinberg, Weissmayer, Schlesinger, and others. Castration has not always proved successful. Much improvement is stated to have followed the application of weight extension to the limbs of a patient during convalescence from this disease. We are indebted to Mr. F. Horsman for the notes of this case.

The patient, a married woman thirty years of age, was admitted to the Hospital for Women and Children, Leeds, in May, 1894. She had never been very strong, but had not had any previous illness except measles. In 1883 she bore a living male child by natural labour, after which she began to complain of pain in the back, passing down into the thighs. Her second child (female) was born in 1886 by natural labour, and was suckled fifteen months. During lactation she felt much pain in the lower part of the back, which was increased by locomotion. After weaning she felt still weaker, and though she could walk two miles she began to oscillate in her gait. Her third and last confinement took place in July, 1888, when a healthy male child was born at full term by a short, easy, natural labour, so that it may be taken as certain that up to this time there was no appreciable amount of pelvic contraction. She remained in bed one month, and felt very weak and ill on getting up. She suckled ten months, but pain and difficulty in walking were now very considerable. During the last six years she gradually reached the condition which she presented on admission to hospital. During this period she had been treated for rheumatism, and had been supposed to have some disease of the cord on account of the altered gait, but the true nature of the illness did not seem to have been recognised. The patient had not known poverty or destitution, but had always been able to procure good food. The house in which the last two confinements took place may possibly have been unhealthy, for it was a farmhouse, and the cowshed was under the same roof. Her condition on admission may be summed up under three heads: (1) signs of softening and giving way of the skeleton, especially of the spine and pelvic bones; (2) pain and tenderness in connexion with the bony parts most affected; and (3) symptoms of constitutional debility and dyscrasia. 1. The patient on admission was thin, and markedly sallow and anæmic. She was weak and ill, and distressed by pain, and her muscles were somewhat wasted. 2. Her gait was peculiar. As she walked her arms, hanging vertically, fell behind the central line of the body, the shoulders being thrown back and the abdomen prominent. She moved along in a waddling-fashion, like an exaggeration of the gait of a very stout woman far advanced in pregnancy. In going up and down stairs she took one step at a time. The knee-jerk and abdominal reflexes were increased. 3. She had shortened stature; her actual height was 59½ in. She said that she and her sister used to be of equal height; her sister measured 62½ in.; hence the patient had lost about 3 in. 4. The spine

was deformed; there was very marked lordosis; the last lumbar vertebra and the upper part of the sacrum were sunken, whilst the lower end of the sacrum was unduly prominent. 5. The thorax was deformed; the upper intercostal spaces were widened, the lower being very much narrowed. The chest was sunken towards the pelvis, so that there was no space between the ribs and the iliac crest, but, on the contrary, the lowest ribs came below that level. 6. There were external signs of contracted pelvis. The symphysis pubis was distinctly rostrated, presenting a very characteristic beak, which could be grasped between the finger and the thumb. The external measurements were as follows: the distance between the iliac crests was 10½ in.; the distance between the two anterior superior spines was 8 in. (this measurement is usually only ½ in. less than that between the iliac crests, so that in this case the iliac spines were rotated inwards and approximated); the external conjugate was 6½ in. In osteomalacia beaking of the pelvis may, as here, prevent any great shortening of the external conjugate. In addition to this, there was sinking in of the great trochanters. In the normal pelvis the intertrochanteric measurement is greater than the intercrystal, and this helps to produce the well-known curve from the waist to the thigh in the female figure. In the present case the body tapered off from the hips downwards and caused a singular and characteristic appearance. The following table gives these two measurements in the patient and in eight other women who happened to be in the same ward at the time. It will be seen that the average intertrochanteric distance in the eight cases is one inch more than the intercrystal, and that in the osteomalacia case it is half an inch less:—

Table of Measurements of Osteomalacia Patient and Eight other Women.

Case.	Intercrystal distance.	Intertrochanteric distance.
1.	11 inches.	12 inches.
2.	10½ "	12 "
3.	11 "	11½ "
4.	10½ "	11½ "
5.	11½ "	12½ "
6.	11 "	12½ "
7.	12½ "	12½ "
8.	10½ "	11½ "
Average ...	11 inches.	12 inches.
Osteomalacia patient ...	10½ inches.	9½ inches.

7. The vaginal examination was as follows. The pubic arch was greatly contracted. The tuberosities of the ischium were nearly together. The tip of the index finger could be just passed under the pubic arch, but not the first joint. When the finger was passed into the vagina it impinged on a round hard swelling which nearly filled the pelvis. This was the sacral promontory and the lowest lumbar vertebra. The first finger could be passed between the sacral promontory and the pubes, but the second finger could not be passed by its side. The available conjugate may be said to be not more than an inch and a quarter. The os uteri was felt below the promontory, and the fundus lay obliquely to the left. 8. There was tenderness of the pelvic bones, vaginal examination gave great pain, especially when the finger was passed between the pubic rami or when the promontory was pressed upon. Walking was painful, so was any jerk of the body, and she said that when she sneezed it hurt her all over. 9. The teeth were so carious that there was not a sound tooth left in the jaws. Menstruation was regular and there was no dysmenorrhœa. The temperature was normal. From these data a diagnosis of osteomalacia was made, and removal of the ovaries was entertained in order to prevent further conception and to give the patient the benefit of a procedure which has recently been followed by such remarkable results. However, the first indication seemed to be to give a trial to simpler measures and to watch the case for awhile. The patient was put upon Parrish's syrup and cod-liver oil. Her weight was now a little under 6st. From this time a steady improvement began. By June 26th she had gained about five pounds, and could sit and walk better. On July 6th she was sent into the country, her weight being 6st. 4½ lb. On Sept. 4th she attended at the hospital. She

¹ This case formed the subject of a paper read before the Leeds and West Riding Medico-Chirurgical Society, Oct. 2nd, 1894.

² *Sajous' Annual of the Universal Medical Sciences*, vol. iii., I., 17, 1894.

had lost almost all her pain, she looked better in all respects, there was a marked improvement in her walking power, and her weight was 6 st. 12 lb. On Dec. 4th the weight was 7 st. 4 lb. and she declared herself to be quite well. The pelvic condition was the same except that there was a great diminution in tenderness. Her present condition (March, 1895) is excellent.

Remarks by Dr. HELLIER.—Osteomalacia is so rarely seen in Leeds that I have ventured to put this case on record, although it is not an example of the most severe type of the affection; and as this disease, especially in its more pronounced stages, is seldom seen by English practitioners, and as the accounts given in English text-books of obstetrics are rather meagre, the following clinical sketch of the disease as seen on the Continent, abstracted from a monograph by Baumann,³ may be of interest. The earliest symptom is pain, which begins in the ischial tuberosities and spreads to the pelvic bones and to the lumbar vertebrae; very soon the hip-joint becomes painful, the movements of the thigh difficult, and the gait slow and shuffling. In the further progress of the disease not only locomotion but also sitting become impossible. The patient is bedridden and can usually lie on the side only, not on the back, because the spine is so tender. Characteristic deformities arise according to the particular bones affected. The promontory of the sacrum sinks into the pelvis and the acetabula also sink inwards. The pubes project like a beak, and the pelvic cavity takes the shape of a heart on a playing-card. There is no one characteristic deformity in this disease, for if the patient can sit and stand the pelvis tends to become flat and the vertebral column to sink downwards and forwards. The normal curves of the spine become exaggerated. The cervical spine may be so much shortened that the chin rests on the sternum. In extreme cases the stature has become a foot less in a few weeks and the sternum has bent to nearly a right angle with apex forwards. Finally, the bones of the extremities bend or break. In consequence of these deformities the internal organs become compressed and displaced, and their functions are interfered with. Hence there may result circulatory disturbances, cardiac obstruction, bronchitis, asthmatic symptoms, digestive disturbances, diarrhoea, &c. Phthisis may come on, or general marasmus may terminate life. If pregnancy occur the pelvic deformity may prevent normal birth, may necessitate Caesarean section, or may cause rupture of the uterus. [Sometimes the contracted pelvis is more or less dilatable in labour.] The bones become bent or partly or completely broken. In the worst cases fractures and curvatures are both found. The bones which go first are the ribs and the bones of the extremities. Callus may fail, or may be so reabsorbed that imperfect union is the result. The mortality of the puerperal form is estimated at 70 per cent. (Litzman). In the non-puerperal variety of osteomalacia the mortality is 84·7 per cent. It occurs in both sexes and in rare cases in young people. Its course is severe. The starting point is almost always the vertebral column or the thorax. The pelvis may escape, but this form is specially apt to extend all over the skeleton, even in rare instances to the bones of the head. The effect of castration upon the course of this disease is one of the most interesting discoveries in obstetrics made in recent years. In 1878 Porro published his improved method of Caesarean section, which, as is well known, involves the removal of the appendages with the amputated fundus uteri, and hence an artificial induction of the menopause. Of 44 cases of Porro's operation published up to 1889, 13 died at the time and 26 recovered from the operation; 5 of these died not long after from various causes (phthisis, Bright's disease, heart disease, &c.). In the remaining 21 a very marked improvement followed in almost every case, and the osteomalacia was practically cured. This does not mean that the deformities disappeared, but that the patients lost their pains and became able to walk and work, that there was no increase in the deformities, but, on the other hand, an improvement in general condition. Naturally the question arises whether simple castration would have the same effect. Fehling and others have tried this in 20 cases, with, it is said, much success.⁵ Dr. Everke of Bochum, in Westphalia,⁶ and Dr. Rasch of London⁷ have also published

successful cases. The old-fashioned Caesarean section, which leaves the ovaries, does not tend to cause improvement in the disease.⁸ Making every allowance for the deductions which experience may demand to be made from the success claimed at first for any new treatment, I think that anyone who reads the details of the cases published will see that while the influence which most tends to make osteomalacia worse is repeated childbirth, that which has most effect in arrest and cure is removal of the ovaries. The good results seem to follow very quickly after the operation, marked relief to the pain often beginning in a week or two, and patients who were entirely bedridden have been able in a few months to walk, to work, and even in one recorded case to dance (Baumann). The causation of this disease is not yet explained; when we consider the list of causes given in text-books our puzzle is increased. If damp, cold, draughty dwellings, hard manual labour, anxiety and worry, bad clothing, poor food, repeated childbirth and hyperlactation will cause it, why do we not find the disease in every large city, where women bear children in rapid succession amidst damp, cold, chill, draughts, rags, and starvation? Surely all the facts of the case, together with the consideration that the disease is notoriously endemic in certain districts and that its sporadic occurrence is very exceptional, point to the probable existence of a micro-organism as the essential factor. It may be urged that this supposition would not harmonise with the effects just described as produced by castration. But a simple explanation of these might be that the condition of the blood in pregnancy and the puerperal state favour the presence and activity of such organisms, and that after the menopause the blood has the opposite tendency. There is nothing extravagant in such a theory. The possibility of spontaneous cure must always be borne in mind, especially in the milder cases. Recoveries from osteomalacia are reported from time to time apart from surgical interference. They may be attributed to various modes of treatment, as, for instance, to phosphorus,⁹ to sea baths,¹⁰ to change of air, iron, cod-liver oil, lime salts, &c., or to the vis medicatrix nature; but it is plain that medical treatment should be tried before surgical. I am especially glad that this was done in the present instance. Had oophorectomy been performed the temptation to cite the case as a convincing proof of the efficacy of the new treatment would have been irresistible, and the patient would have been exhibited cured but without her ovaries, unless, indeed, I had been unfortunate enough to have had to exhibit the ovaries without the patient. Nevertheless, if she should have a relapse and medicinal and hygienic treatment should fail, castration would then, in my opinion, be the proper course to pursue.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Nervous Symptoms and Morbid Changes in the Spinal Cord in Certain Cases of Profound Anæmia.

An ordinary meeting of this society was held on March 26th, the President, Mr. HUTCHINSON, being in the chair.

Dr. JAMES TAYLOR read a paper on Nervous Symptoms and Morbid Changes in the Spinal Cord in Certain Cases of Profound Anæmia. At the commencement of the paper Lichtheim's observations in 1887 were referred to as the earliest recognition of the association of nervous symptoms and spinal cord changes with pernicious anæmia. The subsequent very exhaustive examination of that observer's cases, and of others by his pupil Minnich, was next mentioned. These observations showed that in certain cases of pernicious anæmia symptoms of sclerosis in different areas of the cord were present. The actual degeneration found in the cords, chiefly marked in the posterior columns, was described, and also the conditions found in cords of patients the subjects of pernicious anæmia, but in whom during life no symptoms of cord disease were present. The subsequent confirmatory observations of van Noorden, Eisenlohr, Nonne, and Bowman were briefly

noticed. Allusion was next made to a series of cases published by Dr. Putnam of Boston of diffuse degeneration in the spinal cord in enfeebled persons past middle life, to a case observed by Sir T. Grainger Stewart, ascribed by him to the same class as Dr. Putnam's, and to a case of hyaline degeneration of the cord published by Dr. Bullock. All these cases Dr. Taylor, from a study of the clinical symptoms and of the distribution of degeneration in the cord, believed to belong to the same class as Lichtheim's cases. He next described two cases observed by himself. The first was that of a woman aged fifty admitted to hospital with symptoms of ataxy and in a condition of considerable anæmia. She gradually became weaker, developed excessive spasticity of the limbs, lost control of the sphincters, and died from exhaustion. The cord showed marked degeneration in all areas of the white matter and little or no change in the grey. The second case was that of a man aged forty-three admitted with symptoms closely simulating those of locomotor ataxy. He became gradually weaker, retinal and subcutaneous hæmorrhages were present, and he died from exhaustion. Similar extensive degeneration was found in the white matter of the cord, the cells in the grey matter being unaltered. Dr. Taylor regarded the association of extreme anæmia and spinal cord changes as no mere accidental one. The cord changes he regarded as of double origin: (1) sclerosis resulting from small hæmorrhages similar to those occurring in the retina in the same disease, and (2) sclerosis is the result of a blood state and he instanced as analogous the posterior sclerosis found by Williamson in cases of diabetes and the sclerosis present in the cord in cases of pellagra.

Dr. JOHN HARLEY desired to contribute to the discussion of the general question. Had fatal anæmia any direct connexion with spinal cord changes? In both Dr. Taylor's cases the nerve lesions preceded the anæmia, and in the second case it was only a month before death that anæmia in a marked degree showed itself; so with other recorded cases. From this it appeared that the anæmia was merely the sequel. Did pernicious anæmia induce evidence of spinal cord disease? In six cases of fatal anæmia which he had himself observed there was no symptom of spinal disorder, though sprinkled hæmorrhages were present in the retina and the serous membranes in all the cases. He therefore concluded that the association was merely accidental and not interdependent.

Dr. GOWERS thought that the society was to be congratulated on having brought prominently before the profession facts which raised questions of extreme importance. The problem underlying the questions raised in the paper was similar to that underlying the debate recently held at the society. There was to some extent a similarity of lesions in the two conditions, and also a difference which could not be less significant than the similarity. He desired to point out the salient questions underlying the facts which had been put before them by Dr. Taylor with perfect lucidity and comprehensive grasp. There was, as he had said, a resemblance to the lesions seen in cases with post-syphilitic taint, but this was not always a close resemblance, and there were associated with it changes more or less random in character—changes due to hæmorrhages and the consequences of them. The lines of degeneration found in these cases in the posterior column, or postero-median column, or in the lateral or anterior pyramidal tract resembled in strict localisation the lines of degeneration seen in tabes. In tabes there was a loss of the nutritional influence of the nerve cells of the posterior ganglion, and so also in the case of action of all poisons like syphilis, alcohol, arsenic, lead, and possibly post-diphtheritic poison, and the posterior root fibres going from the skin and muscles to the posterior ganglia would also be affected. Those fibres, he repeated, which were under the nutritional influence of the cells of the posterior ganglion were especially susceptible to most poisons, but the fibres of the pyramidal tract were susceptible to only some of these poisons. In all these instances the sclerosis was a secondary overgrowth of tissue revealed by negative staining in the specimens which had been exhibited, or they could be revealed by positive staining with carmalum. That there must be a toxic agent at work must be admitted, but whether the same toxic agent was the cause of the pernicious anæmia it was not possible to say. In pernicious anæmia there was found structural change in the blood-forming organs, such as the marrow and the spleen. Could such changes occur

without causing also a profound change in the chemical processes of such blood-making organs? It should be remembered in this connexion that the ferment from the diphtheria organisms had been shown to transform the proteid material of the spleen into a poison which acted upon nervous tissues, and among other effects produced symptoms much like those of pernicious anæmia, only more acute. With such a perversion of the process of formation of the blood corpuscles he maintained there would be perversion of the chemical constitution of the albuminous substances of the blood, with the result that a toxic agent would be produced capable of acting on the nervous system in the special way characteristic of such toxic agents. In this way a sidelight was thrown on these affections—on the way in which the sufferer rose only to fall again. Whenever the toxic agent accumulated vomiting and diarrhoea occurred and with it the prostration which ultimately proved fatal.

Dr. W. HUNTER said that the facts adduced were of interest both to the neurologist and to those engaged in the study of the blood. He agreed with what had been said by Dr. Gowers that a toxic agent played a considerable part in the production of pernicious anæmia, and that the toxic agent was due to the absorption of poison of a specific nature from the intestinal tract. From the cases related it was not clear that the relation between the anæmia and the cord changes was a close one, for the cord changes appeared to be antecedent to the anæmia, and in one of the cases related the evidence that the case was really one of pernicious anæmia was not conclusive. He referred to a case of pernicious anæmia which was peculiar in two respects—its association with certain nerve changes and the occurrence of extensive and deep pigmentation of the skin. There was absence of knee-jerk with numbness and tingling of the limbs, and after a first exacerbation there occurred atrophy of the deltoids and of the extensor muscles of the thighs. The degenerative changes in the nervous system might either be due to some toxic change in the blood or to hæmorrhages occurring in the course of the disease. He favoured the view of the lesions being hæmorrhagic in origin, because in cases of pernicious anæmia these changes were few and far between, and recovery from the lesions was good.

Dr. BUZZARD wished to discuss the point whether the anæmia could be a cause of cord changes. In cases of ordinary chloro-anæmia functional troubles referable to the spinal cord were not uncommon, and disappeared when the anæmia passed away; in other words, they were temporary and functional. This bore on the point as to the possibility of cord troubles such as those Dr. Taylor had described being produced by a blood condition. He first referred to the case of a young woman who had all the symptoms of an organic paraplegia. She was suffering from pronounced chloro-anæmia, and she recovered perfectly when the anæmic symptoms were relieved by treatment. In another case a young woman had diminished knee-jerks, and was the subject of chloro-anæmia. Under Weir-Mitchell treatment the knee-jerks returned in full force. A third case occurred in a woman aged twenty-three years. She was admitted to hospital with symptoms which induced them to consider the advisability of an operation for intracranial tumour. There were intense headache, vomiting, double papillitis, and absent knee-jerk. Iodide of potassium being tried without result iron was substituted for it, and there was a very rapid improvement; the papillitis disappeared, the knee-jerks returned, and the blood corpuscles and hæmoglobin rose to their normal ratio.

Dr. MOTT mentioned a case of pernicious anæmia in which the blood corpuscles were reduced to 400,000 per cubic millimetre; the knee-jerks were increased, but there were no signs of spinal cord degeneration. At the necropsy there was found fatty degeneration of the pyramidal cells of the cerebral cortex; possibly later there would have been changes in the crossed pyramidal tracts. He asked if Dr. Taylor had examined these tracts and the ganglion cells of the posterior root. The fibres of Goll's column were the longest fibres going up the spinal cord, and therefore were the most likely to suffer if the centres of nutrition were affected; degeneration could be evident in the peripheral nerves as well.

Dr. BOWMAN said he had examined five cases of pernicious anæmia, and in none of them was affection of the nervous system noted as being present during life. He examined the spinal cords of three of these cases, but no degeneration was found to be present either in the cord itself or in the posterior nerve roots, though Minnich found changes

in the cord in five cases out of twelve in which there had been no nerve symptoms.

Dr. ORMEROD said that the paper constituted an important addition to the etiology of spinal cord diseases. Neither pernicious anæmia nor the form of spinal cord disease described was so common as to warrant the belief that the association between them was a mere chance one. The symmetry of the specimens was against the idea of their being due to hæmorrhage. He examined a case under the care of Dr. Church in which there was a lesion like that shown, but in that case no anæmia was present. A point to be remembered with regard to these cases was that there were very few cases of pernicious anæmia which were not treated with arsenic, and it had been shown that arsenic itself might produce similar lesions.

Dr. TAYLOR, in reply, said that in one recorded case the knee-jerk was at first exaggerated, then it disappeared, and then came back again. The cases were too numerous to be explained by mere coincidence. He had carefully guarded himself in his title from branding his cases as pernicious anæmia, which he thought was at present an indistinct entity. He described his cases as profound anæmia, and one at least of Dr. Putnam's cases was so called. So far the cases were an unexplained series: he had merely drawn the parallel between them, but he did not force it, though he tried to bring his cases into line with those described by Lichtheim and Minnich. The changes were much too symmetrical to be explained by the theory of hæmorrhage. He had not examined the cerebral cortex.

MEDICAL SOCIETY OF LONDON.

Tubal Pregnancy and Case simulating Tubal Pregnancy.—Extra-uterine Gestation operated on in the Tenth Month of Pregnancy.

AN ordinary meeting of this society was held on March 25th, the President, Sir WILLIAM DALBY, being in the chair.

Mr. BLAND SUTTON read a paper on a case of Tubal Pregnancy and one simulating Tubal Pregnancy. A woman thirty-five years of age, mother of two children, the youngest five years old, was suddenly seized whilst "trying on a dress" with sudden severe pain in the abdomen. Mr. Hazel was summoned and found the patient collapsed. At the end of five hours she was blanched, the voice reduced to a whisper, the pulse scarcely perceptible at the wrist, and she complained of great abdominal pain. Since the birth of her last child she had menstruated regularly till January, when her period, which was due on New Year's Eve, failed to appear. Nine days later she was seized with the severe pain which preceded the collapse. On physical examination the abdomen was slightly distended and some dulness could be made out in the left iliac fossa. The uterus was somewhat enlarged, the cervix soft, and the os patulous. As it was clear that the patient was suffering from intra-peritoneal bleeding, probably due to rupture of a gravid tube, abdominal section was performed by Mr. Sutton. On incising the peritoneum a broad stream of arterial blood leaped through the wound and a ruptured gestation sac was detected in the left Fallopian tube. The tube and ovary were removed in the usual way and the blood and clot carefully sponged from the abdomen. The patient rapidly convalesced and discharged the decidua on the fourth day. Sections were cut from the gestation sac and tube and examined microscopically; the sac contained a tubal mole 8 mm. in diameter furnished with chorionic villi. Mr. Sutton stated that this was the smallest tubal mole he had examined. The second case occurred in a patient thirty-five years of age who had been married seven months and believed herself to be three months advanced in pregnancy. She was suddenly seized with severe pain in the left side of the abdomen and metrorrhagia. On examination Dr. Marsden Low made out a swelling in the left iliac fossa, dull to percussion, and smooth and rounded in outline. The uterine fundus could not be distinguished above the pubes. The cervix was so depressed that it could be felt just within the vulva; it was soft and the os patulous; there was also an escape of offensive blood. On examining the patient it was clear that she was pregnant, but whether the fetus occupied the uterus or the broad ligament was by no means certain; further, it seemed that the pregnancy was complicated by a tumour, either a myoma of the uterus or an ovarian tumour. It was decided to examine the case under chloroform next morning and Dr. Champneys was asked to see the patient. During the night she miscarried of a three months fetus

and it was then clear that in addition to the pregnancy there was a large solid tumour in the abdomen. Three days later the abdomen became tender, the temperature fell to 96° F., then rose to 103°, and the patient became extremely ill. Nine days later abdominal section was performed, and Mr. Sutton removed a large pedunculated myoma growing from the fundus of the uterus. The tumour was inflamed and glued to the omentum and intestines by soft, recent adhesions. Recovery was uninterrupted. It was pointed out that the two cases were contrasted because one illustrated the certainty with which rupture of a gravid tube might sometimes be diagnosed, and the other showed how closely such an accident might be simulated by uterine pregnancy complicated by a tumour. The first case demanded decision, the second needed deliberation. The second case was also interesting as an example of the successful removal of a uterine myoma during the puerperium.

Mr. BIDWELL read a paper on a case of Extra-uterine Gestation in which he had operated at the tenth month of pregnancy. The fetus had been dead for some time, and was probably about seven and a half months old. The transverse colon and part of the ileum were adherent to the sac; the former was easily separated, but on attempting to free the ileum the muscular coat peeled off and a rent occurred in the mucous membrane. All the part which had been adherent to the sac, about five inches in length, was therefore resected and the ends united by Mause's method. The patient made an excellent recovery, although a slight fecal fistula appeared on the tenth day and continued to discharge for five days; it was now soundly healed. Mr. Bidwell attributed the success of the anastomosis to the fact that he had excised all the damaged gut and had inserted his sutures into healthy tissues. He did not think that abdominal cases required isolation or special nurses, and if there was no vomiting he treated them as regarded diet in the same way as any other serious surgical case.—Mr. ALBAN DORAN asked why there was so much bleeding from a small ruptured tubal sac. Two days ago while he was operating on such a case the blood spouted out furiously, but in that instance a band passed from the vermiform appendix to the sac. The band was found in reality to spring not from the appendix itself but from its mesentery, and the bleeding came from an artery in this. He thought that tubal pregnancy was much more common now than formerly. Mr. Sutton had done much in clearing up the diagnosis of this subject by showing that the presence of the chorionic villi was an essential diagnostic point. Till recently it was taught that inflammation of the Fallopian tube led to desquamation of the epithelium and then the impregnated ovum coming down the tube would stick at that point; in this way the inflammation of the tube was made to be the primary causative factor. Dr. Webster of Edinburgh had recently adopted a different view. He held that decidual tissue occasionally developed in the tubal parenchyma, and that this might occur all along the tube. In the normal condition of things, when the ovum coming down into the uterus touched the decidual tissue it became adherent there because for some reason the uterine epithelium became lost at that point. According to Dr. Webster this abnormal decidual change in the tube led in a similar manner to the implantation within it of the arrested ovum, and thus a tubal pregnancy was brought about. By this theory, therefore, it was plain that inflammatory disease of the tube or ovum was not necessary to account for the tubal pregnancy, and the inflammation was regarded as a secondary result of the pregnancy. Observations on the condition of the abdominal ostium bore out this theory, for it was usually found that in cases of inflammation of the tubes of the ordinary kind independent of pregnancy the fimbriae were closed, while in cases of tubal pregnancy the fimbriae were usually patulous and the ovum might be extruded through the abdominal ostium into the peritoneal cavity, a condition which had been called tubal abortion.—Mr. HARRISON CRIPPS said that there were two common forms of rupture of the tube—(1) when the rupture occurred on the free or upper border of the tube, and the blood was extravasated into the peritoneum; and (2) when the rupture occurred on the lower border of the tube and the blood passed into the tissues of the broad ligament. In the first variety there was nothing to restrain the hæmorrhage, and the patient was liable to bleed to death; in the second variety, as the broad ligament became distended with blood the pressure arrested the further flow. The symptoms of the first variety were sudden pain and collapse; no tumour could be felt, but there was a general puffiness felt per vaginam and dulness in the flanks.

In the second variety the pain was more acute and of a bearing-down character, but the general symptoms were not so severe. A large firm tumour like a fibroid was felt per vaginam and a tumour could be felt in the iliac fossa on deep palpation. In the first variety it was necessary to operate at once; cases of the second class were best left to nature. There was yet a third variety, where on vaginal examination a tumour could be felt in Douglas's pouch, but no tumour could be discovered in either iliac fossa. In this variety the blood was effused into Douglas's pouch and shut off by adhesions from the general peritoneal cavity. He thought Mr. Bidwell made a mistake to dissect off the intestine; it would have been better to have left a portion of the sac adherent to the gut.—Dr. HERMAN thought that cases of the first variety rarely or ever occurred; it was commoner to get a series of slight hæmorrhages. This was borne out by the observation that the abdomen contained clot of different dates. Cases of this kind had been described by Mr. Taylor of Birmingham. A valuable sign of hæmorrhage into the broad ligament had been described by Mr. Tait; processes of cellular tissue went back to the sacrum on each side of the rectum, and in hæmatoma and cellulitis a ring was formed round the rectum in this tissue which could be plainly felt from the rectum.—Mr. CLUTTON maintained that a considerable number of cases of the first variety occurred, but they came under the care of the surgeon rather than of the obstetric physician. In the autumn of 1894 he saw a case which resembled one of acute strangulation of the small intestine or perforation. The patient was a woman aged forty who had had no children for ten years, but was still menstruating regularly; she had a firm uterine fibroid. The symptoms were vomiting, faintness, and prostration, with acute obstruction of gut, neither feces nor flatus being passed. On opening the abdomen there was a rush of blood and a ruptured tubal gestation was found and removed; the patient recovered. He agreed that it was better to leave a portion of adherent sac attached to the intestine rather than to attempt to separate a firmly adherent gut.—Dr. LEWERS said that two years ago he operated for a right ruptured gestation of three months. He removed the fetus and tube in the usual way, and the patient made a good recovery. A year later she came back with similar symptoms. There was a swelling in the left side of the pelvis, and another in the mid-line. Changes in the breast indicated pregnancy. The day before operation she passed a blighted ovum of the size of a hen's egg. This made no difference to the size of the tumour on the left side of the pelvis, which was found to be a small ovarian tumour, and was successfully removed.—Mr. SUTTON, in reply, said that he was glad to find that surgeons were beginning to take an interest in these cases. He did not think that tubal pregnancy was relatively more common than formerly, but it was certainly more frequently recognised. He referred to two cases in illustration of this. In one case a woman ate a hearty meal of mussels; she was afterwards taken suddenly ill, and was thought to be suffering from poisoning. She died and a necropsy being made on a coroner's order a ruptured tubal pregnancy was found. In another case a woman in Paris was eating an ice at a restaurant when she was suddenly taken ill and died. At the necropsy it was found that she had a ruptured tubal gestation. Cases of the first group usually died unrelieved, while those of the second group went to hospitals and were diagnosed as instances of pelvic hæmatocoele. Cases of the third group had been known for a long time; there first occurred a moderate hæmorrhage from a tubal abortion, then inflammation followed by successive hæmorrhages; these were the intra-peritoneal hæmatocoeles of the obstetric physicians.—Mr. BIDWELL, in reply, said he only attempted the separation of the gut with his finger, but found it to be more fragile than he thought.

CLINICAL SOCIETY OF LONDON.

Nephrectomy for Renal Adenoma.—Cases illustrating Local Treatment by Oxygen.—Syringomyelia with Perforating Ulcer.—Pseudo bulbar Paralysis.—Facio-humeral Type of Myopathy.—Fracture Dislocation of the Spine.—New Form of Aspirating Instrument.—Successful Trephining for Syphilitic Cranial Necrosis.—Meningococle.—A Case of Myosis Fungoides.

A MEETING for the exhibition of clinical cases was held on March 22nd, Mr. LANGTON, Acting President, being in the chair.

Mr. MALCOLM showed a child aged four and a quarter years on whom Nephrectomy was performed for Adenoma two years and four months ago. The interest of the case lay in the long survival of the child after operation. He had removed the right kidney and a tumour which had been regarded as a malignant adenoma, the mass being of oval shape and measuring six inches by four inches. This was done on Nov. 15th, 1892, the child being then under two years of age. When he recorded the case in January, 1894,¹ he thought that only one other child had survived nephrectomy for neoplasm more than a year, in which case death from recurrence had taken place after eighteen months. But, in debate, Mr. Sutton had directed attention to two cases operated on by Dr. Abbe of New York,² in which the children, aged respectively two years and fourteen months at the dates of the operations, had survived. Mr. Malcolm was able, from a private communication, to say that both Dr. Abbe's patients were recently alive and well. One of them would have lived after operation three years on April 12th, 1895, and one was operated on five days after the case he now showed. The patient exhibited was quite well and freely secreted urine of good specific gravity and free from albumen. In answer to Mr. Howard Marsh, Mr. Malcolm said that the tumour in his case had consisted almost entirely of tubules lined by columnar epithelium and elongated processes of epithelial cells which did not show any lumen. As such tumours usually contained also cells resembling striped muscle cells, and as these were absent in this case, he had thought that the peculiar structure of the tumour might account for the good result. This view was negatived by the fact that in one of Dr. Abbe's cases similar tubules were associated with sarcomatous tissue, while the others consisted of striped muscle cells, round and spindle-shaped cells. If the result was not due to some peculiarity in the nature of the tumour the only other suggestion he could make as to the cause of the prolonged immunity was that he had removed the growth very freely, including the capsule and a mass of enlarged glands.

Mr. G. STOKER showed three cases to illustrate Local Treatment by Oxygen Gas. The first case was that of a woman aged fifty-six years, who had for several years been suffering from an intractable ulcer of the leg involving almost its entire circumference. She had been under treatment as an in- and an out-patient for years without any benefit. The limb was immersed in an atmosphere consisting of equal parts of air and oxygen gas. The treatment at once entirely relieved the pain from which she had been suffering; the gas caused a pricking sensation when first turned on, but this disappeared in the course of half an hour. The pus was found to be speedily freed from organisms and the new skin formed was not cicatricial. The second case was that of a man who suffered from extensive and intractable ulceration of the hand, following a poisoned wound of the finger. The rapidity of the healing under a similar atmosphere was remarkable; the nails grew so quickly that they had to be cut every day, and there was an exuberant growth of hair on the back of the hand. By the seventh day the wound was completely aseptic. The third case was that of a girl who had lost nearly all her hair from alopecia areata. The head had been shaved previously, and no hair grew after that till the treatment was commenced. He fitted her with a rubber cap, and into this pure oxygen was pumped. At the end of six weeks she was getting quite a good head of hair.

Mr. MORGAN and Dr. MOTT showed a case of Syringomyelia with Perforating Ulcer. The patient was a man aged twenty-four years who was well until sixteen years of age. Then after a chill he developed perforating ulcer of the left foot, for which the leg was subsequently amputated. Eighteen months ago another ulcer formed on the right foot. The foot was in the position of talipes equino-varus, with pes cavus. There had been no crises.—Dr. MOTT added that there was wasting of muscles of the hand and arms, and the muscles did not react to even the strongest faradaic current, although they did to galvanism. Below the knee there was no sensation of any kind, but in other parts of the body there was dissociation of sensation which was characteristic of syringomyelia. The disturbance of sensation along with the wasting of muscles and the existence of perforating ulcers established the diagnosis.

Dr. MOTT showed a case of Pseudo-bulbar Paralysis in a man aged fifty-three years. Twenty years ago he had suffered from fits accompanied by left hemiplegia and some

¹ Clinical Society Transactions, vol. xxvii.

² Annals of Surgery, Philadelphia, January, 1894.

right paresis. Four years ago it was noticed that the arms and legs were still weak. The knee-jerks were increased, and wrist contraction was marked. There was much difficulty in swallowing, and saliva ran out at the angles of the mouth. On examining the larynx it was noticed that the two sides of the epiglottis fell together. Articulation was very imperfect, and on one occasion he had been fined in mistake for being drunk. The symptoms were possibly due to sclerosis of the pyramidal tracts, which at their decussation might interfere with the glosso-labio-laryngeal nucleus.—Dr. JAMES TAYLOR said that some time since he had seen a somewhat similar case, which Dr. Hughlings Jackson, from the history and clinical appearances, thought was one of pseudo-glosso-labio-laryngeal paralysis—that is to say, a case of double cerebral lesions simulating disease of the bulb, although other physicians who saw it took it to be an ordinary case of glosso-labio-laryngeal paralysis. The cerebral hæmorrhage which ultimately determined the death of the patient rendered it impossible to ascertain what the condition was in the brain, but there was descending degeneration of equal extent on both sides, and the cells of the hypoglossal nucleus were normal. The case shown was similar and the history pointed in the same direction. This patient's voice was very peculiar. He only remembered to have heard that intonation in one other case exhibited by Dr. Ormerod.

Dr. BEEVOR showed a case of the Facio-humeral Type of Myopathy. The patient was a man aged twenty-seven years, who began to feel weak in his legs when fifteen. At twenty he waddled when walking, and at twenty-two he could not walk without help. There was considerable wasting of the muscles of the face, arms, and trunk, and some lateral curvature of the spine with pronounced lordosis. The extreme lordosis was due to weakness of the glutei and rectus abdominis muscles.

Mr. BALLANCE next brought forward a case of Fracture Dislocation of the Spine which had been operated on. The patient was a man aged forty-eight years who fell from a train in rapid motion in November, 1893. He was unable to get up after the accident and he developed cystitis with incontinence of urine and feces. When admitted to hospital he was quite unable to stand or sit owing to loss of power in the lower limbs. Below the knees the muscles were quite paralysed and wasted, and the gluteal muscles were also wasted. Tactile anaesthesia was nowhere absolute, but there were well-defined areas of dissociation of sensation to heat, pain, and cold. The knee-jerks were diminished. The twelfth dorsal vertebra projected very markedly. On Jan. 12th, 1894, seven weeks after the injury, Mr. Ballance made a seven-inch incision with its centre immediately over the projecting vertebra, and removed the laminae and spinous processes of the tenth, eleventh, and twelfth dorsal and the first two lumbar vertebrae. He did not open the theca, but that sheath was adherent to the lamina of the first lumbar vertebra. Two months later the patient had regained perfect movement of the hips and knees, sensation was much improved, and the sphincters were under control. The patient was actually in the condition of a man who had undergone double amputation of the legs below the knees, and he observed that it was quite open to question whether or not he would be better off without the two wasted pegs which were all that remained of the limbs below that level. He could only walk with crutches. He recalled a case in which a patient, who was a footman, had both his feet removed under similar circumstances.

Dr. GARRETT, introduced by Sir Dyce Duckworth, showed an ingenious piece of apparatus by which drainage, aspiration, and exploration could be performed with the same instrument.

Dr. J. B. PARKINSON showed a case of Local Anaesthesia in one Hand. The patient was a young woman aged nineteen years, who suffered from occasional attacks of enlargement and discolouration of one hand, lasting from some hours to several days, specially provoked by cold. The hand became cold and lost sensation. The nerves on the ulnar side appeared to be less sensitive, and pressure on that ulnar nerve did not give rise to any sensation in the hand, as on the other side. She had suffered from amenorrhoea of five months' duration.

Mr. H. W. PAGE exhibited a case of Syphilitic Cranial Necrosis in which there were frequent fits and trephining was followed by recovery. The patient was a man aged forty-one years, who was admitted into his wards suffering from fits which had gradually become more and more frequent; indeed,

he was almost unconscious, being roused only with difficulty. He seemed to be gradually losing ground. There was a history of syphilis and long continued pain in the head. No optic neuritis was present. The symptoms appeared to point to widespread pressure on the brain rather than any definite cerebral tumour. He trephined over the Rolandic area and at once came across some inflammatory material between the scalp and the bone. Having removed the piece of bone he found much broken-down gummatous matter between the bone and the dura mater, of which he removed as much as he could. As the dura mater itself appeared healthy he did not open it. Since then the patient had been free from fits and had had no return of the pain. In 1890 he had a very similar case, in which spontaneous relief was afforded to the pressure by erosion of the bone, but the patient died after a time from pyæmia.

Mr. H. B. ROBINSON exhibited a case of Meningocele. The patient was a child aged seven months, who had first come under his care in December last with a swelling on the right side of the head over the posterior part of the parietal bone. The child was the first-born of a healthy looking mother, and was born after some difficulty. The presentation was cranial and instruments were used. The head appeared to be bruised all over, but most of this swelling soon went away, within the month, leaving the tumour now presented. The mother said that the swelling seemed then about the same size as it was on the first visit to the hospital, about four and a quarter inches by four and a quarter inches (Dec. 4th), and from the time she first noticed it she thought that it "throbbled." On examination the swelling was round and soft with the skin quite free over it. It was placed over or a little anteriorly to the right lateral fontanelle. On deep pressure there could be made out some deficiency in the skull, the edge being very irregular and everted, especially anteriorly; the deficiency seemed to be chiefly in the posterior part of the parietal bone. The skull as a whole was asymmetrical. There were very marked impulse and increased tension on coughing or straining. On pressure when the swelling was lax no definite external pulsation could be made out. Pressure on the swelling did not affect the child at all. There was no history of fits. The tumour had not been tapped. The diagnosis of traumatic meningocele was entertained because of its situation, which was a very rare position for the congenital forms, and from the history of the difficult labour and use of forceps. Such a cause for the traumatic form seemed not previously to have been described.—Mr. MORGAN thought that there was absence of the lateral half of the occipital bone; but whether this was due to the instrumental labour or to want of development he could not say. If it had been an encephalocele it would have increased in size more markedly.—Mr. A. PEARCE GOULD regarded the case as traumatic in origin; he thought he felt a raised rim of bone round the edge and depressed bone within this.—Mr. MARSH suggested that it might possibly be a hæmatocele.—Mr. ROBINSON said that he proposed to tap it shortly with a view to clear up the diagnosis. The extreme tension on coughing and straining was against hæmatocele.

Dr. DE HAVILLAND HALL showed a case of Mycosis Fungoides. The patient was a man aged fifty-two years, who first complained of pains in the arms and legs, to relieve which he rubbed in acetic acid. Between two and three years ago the skin where he had applied the acid began to be affected, especially on the outer side of each arm. The rash spread to the thighs, and in September, 1893, a big swelling the size of a goose's egg appeared on the right hip, and next one on the right elbow. The tumours lasted from six to nine months, some of them breaking down and discharging, others disappearing without going on to that stage. In June, 1894, tumours made their appearance on the feet, head, and face. Since October he had complained of sore-throat, and tumours of the same nature could be seen in the pharynx and on the arytaenoid cartilages.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.

Selection of Cardiac Tonics.—Treatment of Psoriasis by Thyroid Extract.—Aneurysm of the Descending Thoracic Aorta in a Female.

A MEETING of this society was held on March 14th, the President, Dr. J. G. GLOVER, being in the chair.

Dr. ARCHIBALD CHRISTIE read a paper on the Selection

of Cardiac Tonics. He first criticised the methods of employment of this class of drugs. Usually the practitioner prescribed one favourite member of the group, generally digitalis, to the exclusion of the others. In this way the peculiar properties of the drugs were not considered, and it could not be expected that their full benefit would be obtained. The importance of bearing in mind the different factors occurring in any individual case of heart disease—viz., the weakening of the myocardium, the disorder of the cardiac innervation, the condition of the arteries—was strongly emphasised as being essential in choosing the tonic best adapted to the case. The action of digitalis was then illustrated by means of numerous sphygmographic tracings taken during the course of treatment. The disadvantages of digitalis were much insisted on, and especially in cases when for various reasons it was inadvisable to cause a rise of blood pressure, digitalis was the worse cardiac tonic to employ. Strophanthus was the most useful cardiac tonic for general use. Illustrations were given of its use, and the rapidity of its action was brought prominently into notice. Twenty minims of the tincture of strophanthus by mouth produced a distinct effect on the pulse tracing of healthy individuals in fifteen minutes. The actions of convallaria, caffeine, and strychnine were also described and compared. This paper was illustrated throughout by lantern slides of sphygmograms obtained from patients during the course of treatment.

Mr. CHARLES KING described the case of a woman aged fifty years who had for twenty years or more suffered from general Psoriasis in a most aggravated form. There had been practically little relief to symptoms during these years, on many occasions the skin becoming dry, hot, and inflamed, impeding voluntary movements almost completely. After the use of all the usual remedies, in November last she was treated with thyroid extract. At first there was considerable constitutional reaction, but in a short time the psoriasis disappeared, and now the patient is practically well. Mr. King remarked on the value of the use of thyroid extract in chronic scaly skin diseases.

Dr. BURNET and Mr. MACREADY showed the specimen and drawings and gave an account of a case of Aneurysm of the Thoracic Aorta. The patient was a woman thirty-one years of age, who had given evidence of symptoms of serious disease of the thoracic viscera, but none sufficiently definite to allow of accurate diagnosis. She came under observation on account of difficulty in swallowing food and consequent emaciation and weakness. Occasionally this difficulty disappeared, but only to recur. Gastrostomy had to be performed on account of the increasing dysphagia, but the operation came too late, and she died exhausted two days later. After death an aneurysm of the aorta was found in the posterior mediastinum. The oesophagus was compressed between the heart and the aneurysm, and a narrow vertical opening communicated between the heart and the aneurysm, which was blocked by firm coagula in the recent state. The oesophagus at the point of greatest pressure was in a sloughing condition, and was in communication also with an abscess cavity. They remarked on the comparative rarity of aneurysm of the thoracic aorta below the arch, and especially in females. In 167 cases of aneurysm of the thoracic aorta collected by Crisp this combination did not occur once, in 24 cases of aneurysm of the descending portion collected by Dr. Burnet and Mr. Macready it occurred only twice in females.

PATHOLOGICAL SOCIETY OF MANCHESTER.

Epithelioma of the Oesophagus with Perforation into the Trachea.—Exhibition of Specimens.

A MEETING of this society was held on March 13th, Professor SHERIDAN DELEPINE being in the chair.

Dr. LEECH and Dr. GROSVENOR mentioned a case of Epithelioma of the Oesophagus with Perforation into the Trachea. The patient was fifty-five years of age. Three years ago there commenced symptoms of discomfort in the throat and an alteration of the voice. Two years ago he had occasional attacks of choking and difficulty of swallowing, which increased for six months, when it was suddenly relieved. A month afterwards the patient was seized with violent paroxysms of coughing, and he could not swallow even a drop of water, death occurring in six days. Post mortem an epithelioma was found which was situated in the middle of the oesophagus, encircling the tube, and two inches

in length; there was a large perforation into the trachea.—Dr. LEECH and Dr. WILD mentioned a case of ulceration of the oesophagus perforating the aorta and right lung during the course of typhoid fever.

Dr. PERCY ASHWORTH showed specimens of Tuberculous Salpingitis and Peritonitis from a woman aged fifty-seven whose family history was good, but who had married a tuberculous husband, by whom she had five children—the first two healthy and the others tuberculous. When seen seven months before death the patient was greatly emaciated, and the abdomen was filled with fluid. After tapping, a hard mass was found in the pelvis. She was tapped twenty-one times in all; at the thirteenth tapping a hard nodule was discovered in the abdominal wall at the seat of puncture. Post mortem this nodule was found to be a piece of tuberculous omentum adherent to the abdominal wall; the intestines were studded with tubercle, and the pelvis contained a large mass, from the midst of which the two thickened Fallopian tubes, filled with thin pus, could be isolated. There was no doubt that in this case the tuberculous mischief commenced in the Fallopian tubes, and the interesting point was whether the infection had thus been communicated by the tuberculous husband.

Dr. WILLIAMSON showed a Microscopical Specimen of the Phrenic Nerve which presented well-marked parenchymatous neuritis. The specimen was taken from a case of alcoholic paralysis which was under the care of Dr. Steell. During life there had been the usual signs of alcoholic neuritis and finally paralysis of the diaphragm. The anterior tibial nerves also showed marked parenchymatous neuritis. The spinal cord, macroscopically and microscopically, was normal in the cervical, dorsal, and lumbar regions.

Dr. ROBINSON showed a Congenital Malformation in the Heart of a Sheep, and card specimens were shown by Dr. KELYNACK, Dr. MILLIGAN, and Mr. WOLSTENHOLME.

MIDLAND MEDICAL SOCIETY.

Exhibition of Cases and Specimens.—Some Points in Invalid Dietetics.

THE eighth ordinary meeting of this society was held on March 20th, the President, Mr. J. F. CHAVASSE, being in the chair.

Dr. LESLIE PHILLIPS presented a man aged thirty. Four years ago a squarish bald patch came on the occipital scalp, upon which hair has never since grown and which is now hidebound. Two years later a round patch appeared at the vertex, apparently of alopecia areata. The hair has grown here, but a curious ring of baldness exists around it on which pale-coloured hair is now growing. A similar horse-shoe-shaped patch exists at the occiput, and a band over the right ear. This latter gives the impression of partial adhesion to sublying tissue, and pressure here caused pain at the nape. In the right cheek is a vertical band of apparent sclerodermic infiltration. The disease was apparently circumscribed scleroderma simulating alopecia areata, and if this view of the case was correct the regrowth of hair on one patch was notable. The alternative, but less probable, diagnosis given was that morphea and alopecia areata coexisted.

Dr. SHORT showed a man with Violinist's Palsy. The patient, aged twenty-six years, was a jeweller by trade, using his hands for fine work during the day, and for several years he had practised the violin in the evening. He first noticed a sense of numbness between the ring and little fingers of the left hand, followed by weakness of the arm and hand, so that he had to rest his elbow on his knee when playing. The marked features of the case were the absence of spasm or cramps, and the rapid wasting of the thenar, interosseous, and lumbrical muscles. He had been under treatment by massage and electricity for about two months, with marked improvement in the muscular power of the hand.

Mr. JOHN W. TAYLOR showed a Uterus, the seat of Malignant Disease, which he had recently removed by Doyer's operation of vaginal hysterectomy. In this operation the broad ligament is secured by two pressure forceps with elastic blades, and a considerable portion of the ligament may be removed on each side of the uterus without danger of injury to the ureters.

Mr. WOOD WHITE showed a middle-aged woman with a large fungating Epithelioma of the Left Eyelid. The growth had invaded the outer half of both upper and lower eyelids and extended on to the cheek and temporal region.

There were no enlarged glands to be felt. It had been growing for six years.

Dr. DOUGLAS STANLEY showed Cultures in various stages of the Löffler Diphtheria Bacillus.

Mr. HENRY showed a number of specimens illustrative of Injuries and Diseases of the Eye.

Dr. T. NELSON read a paper on Some Points in Invalid Dietetics, in which he reviewed the possibilities of the kitchen in providing a more varied diet for those suffering from fevers, gastric and liver disorders, and other affections. He gave examples of dietaries with methods of preparation of various food stuffs, and concluded by urging some form of instruction in the principles of cookery for medical students as a necessary accompaniment of success in practice.—The President, Drs. Short, Stanley, Puralow, Johnstone, Kirby, and others took part in the discussion.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.

A CLINICAL MEETING of this society was held on March 19th, Dr. S. JOHNSTON, President, being in the chair.

Mr. HORROCKS showed: 1. A case of Lupus of the Tongue. 2. An Epithelioma of the Temple where, after freely excising the growth, skin grafting by Thiersch's method was successfully employed. 3. A case in which the Astragalus was excised for Tuberculous Disease. A transverse incision was made and gauze packing employed for two days, the stitches then being tightened. A good result followed. 4. A case of Epithelioma of the Penis in which Thiersch's amputation was performed.

Mr. CHAPMAN showed (for Dr. MAJOR): 1. A case of Functional Paralysis simulating Sclerosis. 2. A boy aged twelve years with symptoms of Cerebellar Tumour. Twelve months ago there were headache, vomiting, and double optic neuritis; afterwards the sight failed, and now the patient is blind (optic atrophy). 3. A case of Aortic Aneurysm.

Dr. KERR showed: A man with "Habit Spasm" of sixteen years' duration. 2. A girl who had Tetany following a fall on the ice, with injury to forearm.

Dr. A. BRONNER showed cases of—(1) Retinitis pigmentosa, illustrating the early and late stages of the disease; (2) a patient on whom he had performed Stacker's Operation for Disease of the Attic.

Dr. H. BRONNER showed a patient with an obscure Brain Lesion, the symptoms being indistinctness of speech, general mental failure, and implication of the third, fifth, and twelfth cranial nerves on the left side. The probable seat of the lesion was discussed.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Varicocele, Nævus, and Varicose Veins of the Leg.—New Operation for the Cure of Rotation Inwards of the Entire Limb.

A MEETING of this Section was held on March 15th, Mr. W. THORNLEY STOKER, President, being in the chair.

Mr. CHARLES BALL read a paper on the Arrest of Bleeding by Sutures, with special reference to the operations for Varicocele, Nævus, and Varicose Veins of the Leg. In varicocele the mass of spermatic veins is separated from the vas deferens. Clamp forceps are applied above and below, and the entire mass excised *en bloc*; the cut surfaces are now brought together by a very fine continuous suture passed all round the cut extremities and the ends firmly knitted together, the forceps are removed, and if any bleeding takes place additional sutures are put in. No ligatures whatever are used; reliance must be placed altogether on the sutures to stop bleeding, as in the operation for harelip. By this method the spermatic circulation is occluded altogether, the vitality of the testes being provided for by the deferential arteries and veins. Union between cut extremities of the veins effectually braces up the testicle. In a period of five years this operation had been performed nine times with complete cure by primary union, no case of recurrence being met with. In nævus a number of needles are passed under the growth, each of which is threaded with boiled silk. An elastic ligature passed round under the needles temporarily arrests bleeding.

The nævus is excised down to the needles; the elastic ligature is now removed, the needles pulled through, and the silk sutures firmly knotted; in this case also bleeding is controlled by the sutures, if sufficient are put in, and union takes place rapidly. In varicose veins of the leg an incision is made over the portion to be removed, two pairs of catch forceps are applied to the vein, which is divided between them and dissected up to each angle of the incision. Boiled silk sutures are now passed under the entire length of the wound, and the one at each angle is closed, completely controlling the vein, which is cut away close to the sutures; a fine continuous suture is applied to the margin of the wound and the remaining deep sutures closed; here again no ligatures of any kind are applied to the veins.—The PRESIDENT thought that papers dealing with practical matters of detail of this sort were of more interest than the capital subjects of surgery. With regard to the question of the avoidance of ligatures he agreed with Mr. Ball. Quite recently he had written a paper, published in the *Dublin Journal of Medical Science*, on operations on veins. He thought that sutures were better avoided in superficial operations which have to do with veins. Mr. Ball's passage of a ligature under the varicose vein is practically a soft ligature by acupressure. He agreed with nearly all Mr. Ball said on operations for varicocele. In that case pressure applied by a pad low down over the loose scrotum is not suitable. His own practice is to excise from half to one inch of the pampiniform plexus, pass a sterilised catgut ligature round the stump, and ligature the cut ends. He only tied the ligature round the stump tight enough to stop hæmorrhage. The part did not then necrose, and no slough was left.—Mr. BENNETT bore testimony to the success of the cases mentioned by Mr. Ball. What he thought of most importance was his method of dealing with nævi.—Mr. S. M. THOMPSON highly approved of deep sutures.—Mr. KENDAL FRANKS had never tried Mr. Ball's method, but hoped he would have an opportunity of trying it shortly. It was a new method. He did not think there was so much novelty in other matters mentioned in his paper.—Mr. W. THOMPSON thought Mr. Ball's treatment of nævus was the most important practical suggestion. It seemed to him that the ligature had been put upon its trial. Mr. Ball had abandoned the term "ligature" for suture, but he maintained that Mr. Ball was only ligaturing the veins in another way.—Mr. TAYLOR had seen a good many of the cases operated on by Mr. Ball. In the operation for varicocele the catching of the veins by the forceps flattened them out, and so there was a good broad line of union on suturing. The shortening of the cord was important.—Mr. BALL, replying, said that the President had used the terms "necrosis" and "slough" as being practically synonymous terms. He did not agree with this. A necrotic part becomes a slough when it becomes septic.

Mr. SWAN read a paper on a New Operation for the Cure of Rotation Inwards of the Entire Limb after aggravated Equino-varus, with an attempt to explain the anatomy and etiology of the distortion. Mr. Swan showed that the factors of foot inversion commence below the knee. The tibia is in its normal position, but the lower extremity of the fibula is deflected forwards, and is considerably in front of the position which it should normally occupy. This anterior position of the fibula is normally found in the quadrumana, where the foot is used for grasping and is ill suited for walking. Mr. Swan proposes to remedy this condition in man by a careful transverse division of the tibia alone at the junction of its middle and lower thirds. The fibula must be left intact. The lower fragment is rotated outwards and the foot thus brought into a straight position. Mr. Swan has adopted this method in many cases with perfect satisfaction.—The PRESIDENT, commenting on Mr. Swan's paper, thought that his theory of a descent back into lower forms of animal life was very interesting and quite in conformity with the explanation of many deformities.

CITY OF LONDON AND EAST LONDON DISPENSARY.—The annual meeting of this charity was held at the offices, Wilson-street, Finsbury, E.C., on March 22nd, Mr. F. Sharrett presiding. The report showed that the patients' attendance during last year exceeded 42,000. The contributions of subscribing members were £1007, and the awards of the Hospital Sunday and Saturday Funds were respectively £19 and £21. The institution is in a satisfactory financial position, being free from debt and having £1400 invested in Consols. The approaching retirement of Mr. Blunt, the secretary, was regretfully announced, his popularity and ability being heartily acknowledged.

Reviews and Notices of Books.

On the Geographical Distribution of Tropical Diseases in Africa. By R. W. FELKIN, M.D. Marburg, F.R.S.E. Edinburgh: William F. Clay. 1895.

THIS work was originally contributed by the author to the African Ethnological Congress which assembled at Chicago in 1893, while the Appendix, treating of a new method of illustrating graphically the distribution of disease in any area, is the reprint of a paper read before the Congress of Hygiene and Demography at Budapest last autumn. The author, who has a large personal knowledge of Africa, believes in the possibility of its colonisation by Europeans. Thus he says: "Can Europeans become acclimatised in Tropical Africa? My strong opinion is that it can only be possible if migration occurs step by step; and in estimating the possibilities of acclimatisation we must count by generations rather than by years. I believe, however, that our increased knowledge of climatology and hygiene renders the problem of acclimatisation more easy of solution than it was, and, given picked individuals and the careful selection of tropical areas in which to colonise, I see no reason why, with precautions, inhabitants of the temperate zone should not colonise even Central Africa. In the selection of emigrants great care should undoubtedly be taken, and all persons with a tendency to gout or rheumatism, diabetes or albuminuria, those of a nervous or alcoholic family history, or those suffering from either acquired or hereditary syphilis, should certainly be restrained from emigrating to tropical Africa." With regard to the unhealthiness of West Africa the author writes: "Although the West African Coast is called 'the white man's grave,' yet it is undoubtedly true that to a certain extent it is not malaria which causes—or perhaps one should say has caused—the very high death-rate of even 50 per cent. amongst the whites on the coast. In the past, at any rate, this death-rate has been due to the fact of diseased individuals proceeding to Africa, to want of knowledge of the precautions necessary for a residence there, and, unfortunately, in many cases to the wilful ignoring of prophylactic measures and of a well-ordered life." The author speaks very highly of the climate of the Orange Free State, and regards it as an excellent sanatorium for sufferers from pulmonary tuberculosis. Dr. Felkin's map of the distribution of disease is likely to be very useful. The number of different symbols is great, and it requires very close scrutiny to distinguish among them (thus the symbols for scarlet fever and rheumatism, and for syphilis and ophthalmia, seem almost identical), but the information afforded is most valuable.

St. Thomas's Hospital Reports. New Series. 1892-93. Edited by T. D. ACLAND, M.D., and BERNARD PITTS, F.R.C.S. Vol. XXII. London: J. & A. Churchill.

WE learn from the editors' preface that the publication of the present volume has been delayed in order that the statistical reports for 1892 and 1893 and the Calendar for 1894 and 1895 might be included in it. Attention is directed by the editors to the new arrangement of the names of those who have held appointments or who have gained prizes or distinctions in the hospital, and to the local and alphabetical lists of students of the hospital which appear at the end of the volume. About 150 pages at the end are taken up with the Hospital Calendars and purely school matters, of little interest to members of the profession not connected with the hospital. The contents are divided into two parts as usual: contributions from members of the staff and others and statistical reports. In the former are included two papers in Memoriam—W. B. Hadden, M.D. Lond., F.R.C.P., and George Rainey, his Life,

Work, and Character, by Mr. W. W. Wagstaffe (this has been recently specially noted in the columns of THE LANCET). Mr. H. H. Clutton contributes a paper on the Treatment of Hallux Valgus, also a case of Separation of the Lower Epiphysis of the Femur, Amputation, Pyæmia, Gangrene, Death. Mr. W. H. Battle records cases of Traumatic Separation of the Upper Epiphysis of the Femur in Early Life and a case of Acute Bone Inflammation in which a large quantity of Medullary Oil was found in the resulting Subperiosteal Abscesses. Dr. Sharkey writes on Acute Bronchiectasis; Dr. W. H. Tate on Pregnancy in a Unicornuate Bicornuate Uterus; Mr. Edmund White, pharmacist to the hospital, on Sterilised Dressings and Sterilised Water; Mr. C. S. Wallace on a case of Gangrene of the Foot, with Sugar in the Urine, successfully treated by Amputation; and Dr. Cullingworth on the Removal of the Uterine Appendages for Uterine Myoma, with an account of Twenty Cases. In the second part are the statistical reports—Medical, for 1892, by Dr. Hector Mackenzie; for 1893, by Dr. Charles R. Box; Surgical, for 1892 and 1893, by Mr. F. C. Abbott. Midwifery Department: Dr. R. Cory. In-patient Department for Diseases of Women: Dr. Tate. The Ophthalmic Department: 1892, Mr. J. Fisher and Mr. E. P. Isaacs; 1893, Mr. J. F. Rudall. Out-patient Department for Diseases of the Skin: 1892, Mr. W. B. Winston; 1893, Mr. J. W. Hewitt. Department for Diseases of the Throat: 1892-93, Mr. W. P. Purvis. Aural Department: 1891-92, Mr. R. Lake. We are much pleased with the arrangement of these statistical reports, and know of none which are calculated to give greater satisfaction to those members of the medical profession who are anxious to obtain information of value. They are evidently compiled with great care, and must have involved much labour. The result is highly creditable, more especially to those responsible for the reports of the medical and surgical departments. The reports of future years would, perhaps, be improved if, instead of printing long abstracts of cases which have been brought before the societies or published in the medical journals, reference were made to the places where they have already appeared; such reports are read not only by the men of the hospital to which the profession is indebted for them, but by many of those who are in earnest pursuit of professional knowledge. They are also most useful for reference.

On the Natural Immunity against Cholera and the Prevention of this and other Allied Diseases by Simple Physiological Means. By C. GODFREY GUMPEL. London: Williams and Norgate. 1894.

THIS is a learned and at the same time curious pamphlet. It is learned in that its author shows that he is well acquainted with the literature of the subject and with all the latest researches that have been made in regard to it, and curious in that it sets forth an extremely simple view and remedy. Briefly stated, the author's view amounts to this. The rôle of the disease is in the blood, the real cause of death is attributable to the destruction of the blood corpuscles, which swell by the absorption of water, assume a globular form, and burst, allowing the hæmoglobin and potash salts to diffuse in the blood serum; whilst in the globular form the corpuscles have lost their capability of absorbing oxygen and their power of resisting the cholera poison. The presence of sodium chloride in the blood serum tends to counteract this endosmotic property of the corpuscles to absorb water. Ninety per cent. of a population in times of cholera epidemics escape the disease—in other words, are immune to it—and the author concentrates his attention on this and seeks to explain it. Susceptibility to cholera, he argues, indicative of a deficiency of sodium chloride in the system, and conversely the presence of the amount of common salt in the blood that the

system needs the probable cause of immunity from cholera. It follows, if this hypothesis be correct, that the best way of conferring such immunity from cholera, the best prophylactic, is to supply the system with the required amount—a few grains dissolved in cold water and taken every morning before food. We do not at all desire to prejudice the reader by thus curtly expressing the aim and object of this pamphlet. We are persuaded that the author has convinced himself of the truth of the view he advocates, and about which he has written this little treatise, which, apart altogether from the practical point he seeks to prove, is worth reading on account of the nature and variety of the information which it contains. The German edition of this little treatise, its author tells us, was originally written in 1893, and was published in Munich last autumn on the recommendation of Professor Max von Pettenkofer. The literary part of the pamphlet and that which deals with destructive criticism are interesting; it is the constructive part that seems to us weak. To examine and criticise it would take up more space than we can give. Those who care to do so can read it through in a couple of hours, and if they ever have the opportunity and desire to try the prophylactic virtues of the small dose of sodium-chloride recommended they can, at any rate, easily do so without any injury to themselves or anybody else.

Transactions of the Eighth International Ophthalmological Congress held in Edinburgh, August, 1894. Edited by GEORGE A. BERRY, F.R.C.S. Edin., with the assistance of H. PARENT, M.D., of Paris, C. HESS, M.D., of Leipzig, and A. F. FERGUS, M.D., of Glasgow. Edinburgh: Messrs. T. and A. Constable. 1894.

THIS goodly volume, which has been published with commendable speed and accuracy by the editors, contains the papers read before the Congress that met in Edinburgh last year under the genial presidency of Dr. Argyll Robertson, by whom the numerous visitors were warmly welcomed. It contains several interesting papers. Dr. Little of Manchester gives, for example, the results he has obtained from his operations for Cataract for the last five years, during which period he has extracted 428 senile cataracts; 322 of them were performed with and 106 without iridectomy, and it is interesting to find that in the hands of a master the difference in the degree of success is comparatively trifling. In the discussion which followed, Dr. Swanzy and Mr. Critchett expressed themselves in favour of the combined operation, whilst Dr. Noyes, Dr. Knapp, and Mr. Fridgin Teale preferred the simple operation. Professor Leber discussed the proper treatment to be adopted in cases of Perforating Injuries of the Eye by Morsels of Copper, and advocated their early removal by operation. Professor Panas considered the Oculo-motor Paralysis caused by lateral pressure of the cranium, and showed that the greater number of such paralyses were due to fracture of the base of the skull. Dr. Mules describes a new operation for Ptosis, and in a second paper his method of dealing with Ulcers of the Cornea by means of a specially prepared gelatine wafer. Mr. Marcus Gunn contributes an article on the Changes in the Macula associated with Retinal Inflammation and Oedema. A paper that led to some interesting discussion was by Dr. Benson of Dublin on Recurrent Temporary Visual Obscurements, with the ophthalmoscopic appearances observed during the obscurations, which are probably of vaso-motor origin. Mr. Juler supplies a contribution to the Anatomy and Physiology of the Iris, in which he describes a dilator muscle of the iris. The Mechanism of Accommodation is the subject of a paper by M. Tscherning. Dr. Bull draws attention to the effects of Lid Pressure on the Cornea. Histological papers on the Structure of the Ganglion Cells of the Retina and the disposition of Schlemm's

Canal are given by Dr. Bach and Dr. Gutman. The treatment of strabismus by advancement instead of tenotomy is ably advocated by Dr. Landolt in a paper on Strabotomy. Dr. Darier of Paris contributes a paper on the Best Methods of applying Mercury in Ocular Therapeutics and discusses the relative value of innunction, hypodermic injection, intra-ocular injection, and subconjunctival injection. It would appear that, whilst in many cases these methods of treatment are very efficacious, in others severe irritant symptoms are apt to be set up which may prove troublesome, and rather larger experience than we at present possess is required before they can be recommended with confidence.

We cannot pretend to give a full list of the sixty or more papers that are contained in this volume, but many of the articles deserve careful study by every ophthalmic surgeon. The Congress appears to have been a highly successful one, and it was agreed that the next Congress should be held at Utrecht, the date being at present not definitely settled.

Essays on Rural Hygiene. By GEORGE VIVIAN POORE, M.D., F.R.C.P. Lond. Second Edition, with Thirteen Illustrations. London: Longmans, Green and Co. 1894.

WE are not at all surprised at the appearance within eighteen months of a second edition of this work, for it contains a large amount of interesting and instructive matter based upon the results of reflection and experience on the part of a bold and original thinker. The author has added a large amount of new material to the present edition of his "Essays on Rural Hygiene," and omitted some which had previously appeared. What he has to say is well worth reading, and as the book has the merit of being vigorously and pleasantly written the reader's interest is stimulated and sustained. Sanitary defects, difficulties, and shortcomings are tersely described, and the way in which the author would have them dealt with is set forth in a clear and practical manner. The chapters on concentration of population in cities, "the living earth," practical details, and personal experiences are written in a fresh and excellent way. But our readers should peruse the volume and judge of its merits for themselves.

Analytical Records FROM THE LANCET LABORATORY.

(1) LIQUOR CINCHONÆ HYDROBROM (FLETCHER).

(2) CINCHONA WINE (FLETCHER).

(FLETCHER, FLETCHER, & CO., HOLLOWAY, N.)

MESSRS. FLETCHER have recently added an important new member to their well-known list of syrups of the hydrobromates, of the value of which we have before expressed a favourable opinion. In the new preparation (liquor cinchonæ hydrobrom.) hydrobromic acid is employed as the solvent of the active principles of cinchona bark, so that it contains amongst other less well-defined constituents the whole of the alkaloids of cinchona, together with the kinic, kinovic, and cincho-tannic acids, which contribute important aromatic and tonic properties not possessed by the chemically separated alkaloids themselves. The hydrobromic extract is a dark reddish-brown, syrupy liquid, acid in reaction, and turning nearly solid on the addition of alkalis, the mass yielding an abundance of alkaloid when the proper solvents are used. Bromine was recognised, but with some difficulty, owing doubtless to the complexity of the preparation. The extract remains perfectly clear, even when largely diluted with water, and is not unpleasant to the taste. It is sufficiently stable to allow of combination with a well-chosen wine, samples of which we have also

examined. On analysis the Cinchona Wine gave the following results: alcohol, by weight 13.38 per cent., by volume 16.52 per cent., equal to proof spirit 28.95 per cent.; extractives, 17.80 per cent.; mineral matter, 2.45 per cent., consisting largely of the potash salts of the bark. Its composition indicates the employment of a good class of port wine for this purpose, each wineglassful being equal to ten minims of the hydrobromic extract, or the equivalent of ten grains of selected cinchona bark. It is an agreeable tonic and invigorant. Not the least interesting and important feature of the extract is that it is perfectly compatible with iron compounds, more particularly with the bromide, no precipitate or even a blackening in colour being produced, as in the case of ordinary alcoholic extracts. This combination of cinchona with hydrobromic acid is designed to obviate the distressing symptoms which, as is well known, frequently follow the exhibition of quinine or its allies—an advantage which, we learn clinical experience has proved it to possess. Liquor cinchonæ hydrobrom. (Fletcher) is calculated to remove a drawback, therefore, which has debarred many from deriving the antiperiodic, antipyretic, and tonic properties for which cinchona bark is chiefly valued.

ALPHA GUAIACOL (SYNTHETIC CRYSTALLISED).

(A. CRAMPIGNY & Co., PARIS. LONDON: WILCOX AND Co., 239, OXFORD-STREET, W.)

Most chemical works of reference describe guaiacol—the methyl derivative belonging to the group of diatomic phenols, of which catechol and resorcinol are members—as a strongly refractive liquid. It is prepared synthetically in the form of well-defined crystals, which melt at the temperature of the hand, the liquid boiling a few degrees above 200° C. It crystallises at 28° C., although a lower temperature is necessary for recrystallisation. On dropping, however, a crystal into the liquid at 15.0° C. the entire mass soon solidifies, the temperature rising to nearly 30° C. An aqueous solution of these crystals, we find, gives a mahogany colour with iron perchloride, and an emerald green changing to olive with concentrated sulphuric acid. Guaiacol is a powerful antiseptic and disinfectant, and has been used as an inhalation in phthisis. On applying it to the skin it is said to exert powerful antipyretic effects in febrile disorders, more especially in tuberculous. Its use in dental treatment is also well known. Since, however, it has been obtained in a pure crystalline form guaiacol, or alpha guaiacol, as the above makers prefer to distinguish it, will probably find a wider field of usefulness in the treatment of disease, especially as hitherto its uncertainty of composition, as represented in creasote, afforded no guarantee of uniform and constant results. For internal administration it is used in capsules.

LIQUORICE EXTRACT (SOLAZZI).

(STREET BROTHERS, 5, SKELLS-STREET, LINCOLN'S-INN, W.C.)

The dried extract of liquorice root, generally sold in sticks, has frequently been the subject of very considerable adulteration, the adulterant commonly found being entirely inert medicinally, and being in most cases some form of starch. The above brand has long been known to be of standard purity. We found the specimen to be completely soluble in water and entirely free from impurities of any kind. It is, therefore, well adapted for the pharmaceutical purpose for which it is so useful, while as a popular demulcent it is both safe and reliable.

HUMANISED MILK.

(THE ATLESBURY DAIRY COMPANY, LIMITED, 31, ST. PETERSBURGH-PLACE, BAYSWATER.)

Samples of this milk were kept in the Laboratory for several weeks before being opened, at the expiration of which time the contents were found to be perfectly sweet and in good condition. The bottles are closed by a metal cover fixed upon a rubber band by atmospheric pressure, the space within being exhausted of air. On piercing the lid with a sharp-

pointed instrument air rushes in, and the cover may then be easily removed. The following analysis shows how well adapted this preparation is for infant feeding: total solids, 11.42 per cent.; fat, 3.70 per cent.; mineral matter, 0.47 per cent. Its composition is evidently based upon well-ascertained physiological requirements. The milk is sterilised and we could trace no preservatives, two points which accentuate its value and excellence as an infant food.

New Inventions.

THE GLOBE NEBULIZER.

MANY of the various forms of spray-producing or "atomising" apparatus resemble each other in projecting a more or less forcible stream of medicated spray carried by a current of air or steam. The instrument under notice acts on a somewhat different principle, the forcible jet of spray being produced within a globular vessel furnished with a caoutchouc tube through which the patient breathes quietly, inhaling an atmosphere charged with a vaporous cloud or mist derived from the solution employed. Only a small quantity (less than half an ounce) of the medicated solution is put into the bottle and is sprayed by a current of air supplied by an ordinary valved caoutchouc ball worked by hand. The spray being driven against the inside of the bottle is further com-

minuted and is quickly felt in the naso-pharynx of a person breathing through the tube. Alcoholic solutions of oleo-resins are, from their physical properties, well adapted for use in this apparatus. One of the formulæ recommended for cases of bronchial and catarrhal affections consists of menthol crystals, oil of "Scotch pine," of eucalyptus, and of cassia, dissolved in tincture of benzoin. Other formulæ have "fluid petrolatum" as the solvent, and to others glycerine is added. Several of the stock solutions contain iodine, carbolic acid, cocaine, quinine, antipyrin, &c. A nickel-plated inhaling mask is supplied for ordinary use, as well as vulcanite tubes applicable to the nostrils and the ear. When the breathing-tube is detached and the hand-ball vigorously worked, the "nebulized" vapour issues from the short outlet tubes like a faint cloud of pale smoke. The designer is Dr. H. M. Dunlap, an American physician, and the London agents are Messrs. Oppenheimer, Son, and Co., Limited, 14, Worship-street, E.C.

NEW SAFETY BOTTLE.

MR. PADMORE, 84, Regent-street, Leicester, has brought out a novel and very simple contrivance for guarding against mistakes in the handling of bottles which contain poisons. The neck of the bottle below the lip is cylindrical for a length of about an inch, as is the case with very many ordinary bottles, and this part is encircled by a loose collar of tinplate, to which a swinging cap covering the cork is attached by means of a wire. Previously to removing the cork this cap must be turned aside out of the way, and a further means of attracting the attention of the careless is provided by the fact that the tilting of the bottle in pouring out the contents causes the cap and loose collar to fall in the way of the issuing fluid, so that they have to be turned round and held up between the finger and thumb before a glass or cup can be filled. The attachment does not in any way interfere with the replenishing of the bottle, and by its use it would seem that the most inattentive, even in semi-darkness, could hardly confuse ordinary draughts or mixtures with liniments or medicines of exceptional strength.

THE LANCET.

LONDON: SATURDAY, MARCH 30, 1895.

ON Thursday next, April 4th, the Council of the Royal College of Surgeons of England will proceed to the election of a President in the place of the late Mr. JOHN WHITAKER HULKE, whose death while worthily holding the reins of office was a subject of recent regret to the profession which he dignified with his character and ornamented with his learning. For what qualifications should we look in Mr. HULKE'S successor? He should have been a member of the Council for some years, so that he may have become fully acquainted with the working of the body over the deliberations of which he will have to preside. He should, if possible, still be engaged in active hospital work, so that as an administrator, a teacher, and a practical surgeon alike he may remain in touch with the hospital of the day, the student of the day, and the surgery of the hour. He should have also been a member of the Court of Examiners for a reasonable time so that the work which is, at any rate at a superficial glance, the most essential work of the College—the examination of candidates—may be familiar to him; and it is well that he should be a ready and eloquent speaker. It is also desirable that he should reside in London, for the almost daily attendance at the Royal College of Surgeons, which is needed for numerous small but important matters, would be a very arduous task to a member of the Council continuing to live in the provinces. There are four members of the Council who suggest themselves to us as proper candidates for the office of President, inasmuch as each fulfils most of the conditions we have indicated above. These gentlemen are, taking them in the order of seniority of election to the Council, Mr. THOMAS SMITH, Mr. CHRISTOPHER HEATH, Sir WILLIAM MACCORMAC, and Mr. REGINALD HARRISON.

Mr. THOMAS SMITH, the senior surgeon to St. Bartholomew's Hospital, was first elected a member of the Council of the College in 1880, and was re-elected in 1892; and in 1887 was Vice-President. Mr. CHRISTOPHER HEATH, the senior surgeon to University College Hospital, joined the Council in the year 1881, was elected a member of the Court of Examiners in 1883, and was Vice-President both in 1888 and in 1892. Sir WILLIAM MACCORMAC was elected to the Council in 1883, and re-elected in 1891. He has twice held the office of Vice-President—in 1890 and 1893. He became a member of the Court of Examiners in 1887, and, being re-elected in 1891, still continues a member of the Board. Though no longer on the active surgical staff of St. Thomas's Hospital, the interval is so short since he resigned his post that the resignation cannot be considered any serious objection to his claims. Mr. REGINALD HARRISON became a member of the Council in 1886, and was re-elected last year; for the present year he is one of the Vice-Presidents. Mr. HARRISON holds no appointment at a general hospital in London, but he has made an excellent reputation as surgeon and examiner in

the provinces. Any of these members of the Council would fill the post satisfactorily, but Mr. THOMAS SMITH has, it is said, no intention of becoming a candidate for the position, and if this be so it seems to us that the choice of the Council will probably fall either on Mr. HEATH or Sir WILLIAM MACCORMAC. Both have been members of the Council many years, both have acted as examiners and have held the office of Vice-President, and both occupy prominent places in the estimate of their profession as scientific surgeons.

The position of President of the Royal College of Surgeons of England is one of great and growing importance, for the President is not merely the titular head of a Royal College, but the official representative of surgery in England. There was a time, as is known to all our readers, when it was customary for the Council of the College to elect to the Presidency, as a matter of course, the senior member of their body who had not already held the office. This custom was broken through a few years ago, and the old method has happily never been reverted to, for it could not but detract from the honour and credit of the office for its possessor to hold it merely through a routine method of election; but the election still rests with the Council, and, unlike the sister college, the Fellows have no direct voice in the choice of their own President. Our views on this and cognate points in the administration of the College have been and are constantly before our readers, and this does not seem to us a particularly apt time for their recapitulation. We have also purposely refrained from dilating on the views held by the gentlemen whose names we have mentioned on college politics, because we feel certain from indications whose significance can have escaped but few that there will no longer be any bigoted resistance on the part of those in power to the just reforms which have so long been demanded and must eventually be conceded both to the Fellows and to the Members.

THAT the nosological position of so common and familiar a disease as acute rheumatism should even now be undetermined may seem strange, but is not inexplicable. For in the case of rheumatism there has been no such clinching demonstration of primary blood change made as in the memorable discovery in gout of uric acid in the blood, and its deposit in articular and fibrous tissues by Sir A. GARROD—a discovery which once and for all determined the nature of that malady. The fact that in rheumatism, as in gout, the most obvious changes are arthritic has long tended to a confusion based upon theories on diathesis which we are fast leaving behind. Rheumatic fever must be regarded as a disease *sui generis*, and the sooner it is detached from other joint diseases that go under the "rheumatic" name the clearer will be our conceptions of its nature. The imperfections of a nomenclature which is based on partial knowledge not only tend to perpetuate erroneous ideas of morbid affinities, but must be taken into account as knowledge widens. The old terms—sanctioned by long usage—cannot be dissociated from the conditions they connote, but they must be given new meanings, even if this involve an entire severance from their old-established relationships. This appears to be eminently the case with the term "rheumatism," that embraces

many conditions now known to be of widely differing pathogeny. Regarding solely the leading instance of the group of so-called rheumatic affections—namely, acute rheumatism—it is instructive to observe how many and varied have been the views advanced to explain its origin. The name implies an affinity to catarrhal states, of which the existing cause is held to be a “chill”; the *modus operandi* of this chill being explained in various ways—e.g., a suppression of cutaneous functions, a disturbance of nervous mechanism, or a perversion of muscular metabolism. That the stress of the resulting inflammatory reaction falls upon articular structures is accounted by some as evidence of an underlying arthritic diathesis, by others as proof of disturbance in the central nervous apparatus controlling the nutrition of joints, and by others to the special predilection of excess of lactic acid in the blood to excite arthritis. There is no gainsaying the fact that theories such as these have each more or less plausible support in what is known of the etiology and intimate pathology of the disease, and some—e.g., the lactic acid theory—have been put to the test of experiment. Yet when a broader view of the subject is taken, and an attempt is made to harmonise these explanations with all the known facts concerning rheumatic fever, it is seen how one or other hypothesis fails to account for all its phenomena. Even the common exciting cause of chill is sometimes lacking; whilst, as is well known, arthritis in some cases, especially in the young, may form but a fleeting part of the disorder or be practically absent. Hence the endeavour to ally acute rheumatism more with the great group of zymotic or infective diseases, which implies that whatever may be the internal changes that characterise it these alone do not form its whole pathology, but that the initial factor is the introduction from without of a specific agent. It was to the exposition of this view of the nature of acute rheumatism that the Milroy Lectures, lately delivered by Dr. NEWSHOLME before the Royal College of Physicians of London were devoted; and, although the doctrine itself is not original (it was held formerly by Dr. FARR, as the lecturer stated, and has been advanced by many recent writers), it has not hitherto been supported in so exhaustive and complete a manner, for Dr. NEWSHOLME recognised clearly that in order if possible to justify the claim to range rheumatic fever among zymotics it must be proved to have affinities with the commonly accepted attributes of the whole class, and be not simply characterised by certain isolated features, either etiological or clinical, which may point to the probability of this alliance. The thesis which he ably sustained was to the effect that “rheumatic fever is a specific febrile disease caused by introduction from without and multiplication in the system of a pathogenic microbe, endemic in Europe and America and other parts of the world, but at varying intervals excessively prevalent, epidemic, or even pandemic.” It would be impossible to pursue the whole of his instructive and weighty demonstration of the truth of this proposition, but we must be content to treat of what seem to be the three main lines of argument which he advanced—viz., those based (1) on epidemiology; (2) on environment; and (3) on clinical and pathological observation.

The argument from epidemiology which Dr. NEWSHOLME placed in the forefront, and to which he devoted

much consideration, opened up practically new ground. He had collated statistics upon the prevalence of the disease from all sources, and marshalled them in a manner which few could emulate. The diagrams which he constructed from these statistical facts were most telling in their uniformity. For whether—as he was perforce compelled to do—he utilised only the death returns in various countries, or dealt with hospital statistics of the cases of rheumatic fever admitted, or with the notification returns of Scandinavia, the main result was to show that, in certain years there was very marked rise in prevalence as compared with other years—so marked, indeed, as to justify the application of the term epidemic to them, on the same ground as it is applied to the years of excessive prevalence of zymotic diseases in general. Due allowance was made for obvious sources of fallacy, such, for example, as the varying fatality of the disease, where death returns only were available, and the assumption that cases treated in hospital are at all proportionate to the prevalence of the disease in the places concerned; and it is quite likely, as Dr. NEWSHOLME suggests, that a smaller proportion of such cases now find their way into hospital wards than formerly. The concordance in the results of such an inquiry is all the more striking in face of these and other difficulties; and we are glad that the annual reports issued from our hospitals should have been utilised in this manner. There are many moot points in the statistics of disease which could be determined by a similar analysis of hospital reports; and if it were possible to have greater uniformity in the plan of compilation of the returns of various hospitals their value for this purpose would be enhanced. As regards the question before us, it may be urged that the excessive prevalence of a disease does not prove that it occurs in epidemic form, but that it may depend on variations in seasonal or other conditions. To this it would be equally right to assert, as we take it Dr. NEWSHOLME practically does, that marked excess in prevalence is what is meant by “epidemic,” which may or may not have such determining conditions behind it.

To pass to the argument from environment it would be absurd to maintain that a disease can have no specific character because of its prevalence being apparently related to conditions of soil, climate, or weather, although the independence of a disease of of such conditions may go far towards suggesting its specific or zymotic character. Thus, no one doubts the specificity of tuberculosis, but the prevalence of phthisis has been clearly shown to be influenced by soil conditions; malarial diseases are bound up with the states of air and soil of infected districts, and no one doubts their specific nature; it has been proved that the weather conditions favouring bronchitis are not precisely those which are associated with the prevalence of pneumonia, and yet the evidence in favour of the specificity of the latter is on other grounds practically convincing. The seasonal prevalence of rheumatism may not then be taken as proof of its non-zymotic character, provided other and stronger evidence in favour of the alteration be forthcoming. Dr. NEWSHOLME'S researches have shown that there is a very definite relationship between deficient rainfall, low ground water, and high soil temperature on the one hand and the prevalence of rheumatic fever on the other. This result is unexpected, but it is supported

by facts which cannot be gainsaid, and he has applied it to the explanation of the nature of the disease that he adopts.

In considering the argument from pathology and therapeutics, it must be admitted that no theory of rheumatism is so well able to account for its clinical phenomena as the one which refers it to an infective agency. Considerations based upon changes in blood or nervous system fail to embrace its multifarious manifestations. The type of the pyrexia—the articular and, above all, the cardiac inflammation—are best explained on the microbic doctrine. Indeed, so far as bacteriological investigations go—and their results are by no means so uniform or conclusive as to set the whole matter at rest—the occurrence of endocarditis would seem almost to necessitate some such agency. But Dr. NEWSHOLME takes us further. He dwells on the fact of the relationship between tonsillitis and acute rheumatism, as suggesting that it is through the tonsil that the rheumatic microbe enters the system; but we confess that here he has probably exceeded his warrant. For, frequent as tonsillitis or mild sore-throat may be in conjunction with the onset of an attack, it is not so pronounced a feature as to be deemed a necessary and essential part of it. Nevertheless, we may admit that the liability to relapse, as well as to second and later attacks, although not concordant with many proved infective disorders, does not suffice to remove acute rheumatism from this category; whilst the factor of heredity can, we do not doubt, be found—to a much more limited extent, it is true—in many other diseases of admittedly specific origin. The marked anti-rheumatic action of the salicylates has been explained on chemical grounds by Dr. LATHAM, but was claimed long since by Dr. MACLAGAN, as it is now by Dr. NEWSHOLME, in proof of the microbic view.

On the whole, it is impossible to peruse these admirable lectures without being largely impressed with the force of the arguments and evidence which they contain, and whatever the precise position of the disease may be amongst the zymotics—whether it is more allied to the miasmatic than to the contagious class, or whether its microbe is bacterial or protozoal—that it is more reasonably placed here than elsewhere in the nosological list seems to be well-nigh proved. When this is quite assured it will be time to reconsider the position of the other forms of disease known as “rheumatic,” but which have no real relationship to the malady hitherto taken as their prototype.

SLEEP is a greater mystery than insomnia. We hear much of the latter state in these days. But it is more wonderful that we sleep so well than that we are occasionally wakeful. We hear more of sleeplessness than our forefathers did. It is a remarkable fact that in scarcely any of the older recognised text-books of Practice of Physic is there any formal notice of insomnia *per se*. In later works, and especially in those devoted to treatment, the subject of insomnia does receive considerable attention. And every now and again the sleeplessness of a great man in the world of science or in that of politics reminds us that eminence has its troubles, and of a sort which seldom affect the poor man. It is probable that this evil of wakefulness is more common than

it used to be. The excitements, and especially the worries, of life multiply. Many of the arrangements of society are of a nature to drive away sleep. Even the very pleasures of life are so taken by many as to rob them of one of the greatest pleasures of all—an eight hours' sound sleep; for we maintain that this is what everybody should aim at. It may seem a long time to spend a third of one's life in sleep. But if the other two-thirds are used well there is little cause for blame. No rule for all can be laid down; but it would be well for most people in the intensive days in which we live to devote eight hours to the cultivation of the mood and act of sleep, and to resist the domination of all habits and fashions that are inconsistent with this purpose.

Insomnia is not necessarily to be treated as a disease by itself. It may sometimes even be corrected without the aid of the medical man, by a little common sense and prudence on the part of the patient. The great danger of acting without medical advice is that mere drugs are apt to be regarded as the remedy, and the most obvious causes are apt to be overlooked. There cannot be a greater mistake than for a sleepless person ignorant of medicine and more ignorant of disease to take one after another the advertised and vaunted medicines which are supposed to procure sleep. The last state of that man is likely to be worse than the first. If there is one thing on which therapeutists are agreed it is that such medicines constitute but a small part of the treatment of insomnia, and require extreme care in selection and in use. Some eminent men in our profession have carried this objection to great lengths. They were satisfied that the cure of sleeplessness lay in other directions and that a little sleep procured without such means was better than twice the amount produced chemically. Some of these medicines are practically useless; others are actually dangerous in themselves and in their immediate effects. All of them are liable to the objection that their action is attended with a certain fascination which is apt to engender a liking for frequent repetition of the dose. Clearly the use of such agents should be controlled severely by medical prescription. If the abuse of them goes on as it is going at present the Poisons Act should be extended so as to include this whole class of drugs.

Insomnia is really a mere symptom and will no more be treated *per se* by the intelligent practitioner than the eruption of an infectious fever or the diarrhoea of typhoid fever. The great duty of the medical man is to trace it to its causes and its associations, and to deal with these. If it follows influenza it must be regarded like all the other *sequela* of that protean disease with some patience, but with much conviction that it will yield, sooner or later, to sound treatment. A very important point is to ascertain whether the insomnia is attended with pyrexia or otherwise, for of all means for producing restlessness and marrying the night's repose an increase of two or three degrees in the temperature is among the most effective. Apart from general pyrexia, it is well to note all local peculiarities of heat, whether in the direction of excess or defect—cold feet, a hot head, &c.—and to deal with them accordingly. It is, of course, equally important to ascertain any error of function that can reasonably be associated

with such a symptom. Such errors may frequently be found in the gastric or renal or hepatic functions, and their removal will quickly alter the whole complexion of the patient's life by night and day.

No treatment of a sleepless patient can be satisfactory which has not strict reference to the particular patient, to his constitution, his habits, his idiosyncrasies, and his pursuits. No details bearing on diet or surroundings must be overlooked. The physician will not needlessly interfere with any legitimate pursuits or even habits; but, on the other hand, he will be firm in suggesting reasonable changes dictated by a medical survey of the patient's condition. While interference with a patient's necessary business or pursuits is objectionable as tending to aggravate his complaint there should be no hesitation in laying down rules with regard to diet, stimulants and general environment. We may be asked, Is there to be no place for hypnotics and narcotics in such cases? Our answer is simple. They are not excluded; but they should be used only as a secondary and subordinate means after the failure of other means, and they should be used only under medical sanction. We will not attempt to dictate to the profession which drug is most safe or least objectionable. That is a part of the daily study of every medical man. But we are persuaded that the use of "sleeping draughts" will be reduced to a minimum by those practitioners who best realise the normal conditions of healthy sleep and the advantage of so using their influence over their patients as to bring them well within reach of the attainment of those conditions.

Annotations.

"Ne quid nimirum."

THE NATION'S CONSUMPTION OF ALCOHOL, TEA, AND TOBACCO FOR THIRTY-TWO YEARS.

A RECORD of the consumption from 1861 up to the present time of tea, coffee, cocoa, and chicory, of alcoholic beverages, and of tobacco, compared with the increase of population, should be of interest to all classes: to the social reformer, because he may be able to form some estimate of the moral progress of the community based on the figures dealing with the consumption of intoxicating drinks; to the economist, because he may find interesting information on the revenue accruing from duties; to the hygienist, because he may make some valuable deductions bearing upon the relation to health of the increased or decreased consumption of alcoholic and non-alcoholic drinks and of tobacco; and lastly to the intelligent public, because, to some extent, the return is a gauge, so to speak, of the moral, social, and financial condition of the people as a nation, as well as of its prosperity. The most striking feature in the purely diagrammatical return, which has been recently issued and which has been ordered by the House of Commons to be printed, is that while an enormous increase in the consumption of tea, coffee, &c. has taken place—the line illustrating this extending as a diagonal across the diagram till it reaches the top right-hand corner (1893)—there has been a steady diminution in the consumption of both beer and spirits, the lines indicating the last two being practically parallels not only with one another, but approximately with the base of the diagram also. Between 1861 and 1862 the total consumption

of tea &c. was 120,000,000 lb.; it then steadily rose until in 1893 it stood at 265,000,000 lb. In the same period the population increased from 28,500,000 to 38,500,000, so that while in 1861 the consumption of tea &c. per head was 4.33 lb., in 1893 it was 6.90 lb. In regard to wines and spirits, the consumption in 1861 was equal to 35,000,000 gallons, with the population at 28,500,000, and in 1893, with the population at 38,500,000, the consumption was 52,000,000 gallons, so that per head it was equal to 1.22 gallons in 1861 and in 1893 to 1.35 gallons, the highest record being 1.80 gallons in 1876, since which the consumption has steadily diminished. The consumption of beer exhibits a similar rise and fall. Thus in 1861 the amount consumed per head was 24.3 gallons, in 1874 34 gallons, and in 1893 29.6 gallons, the total consumption varying from 20,000,000 gallons in 1861 to 31,000,000 gallons in 1876 and 32,000,000 gallons in 1893, the population having increased by 10,000,000. Coming to tobacco, in 1861, when the duty was 3s. 1½d. lb., the total consumption was 34,000,000 lb., being equal to the use per head of 19½ oz.; in 1863 the duty on cigars was reduced from 9s. 5½d. to 5s. per lb., and the consumption then rose to 21½ oz. in 1865 to 23½ oz. in 1877. In the following year (1878) an increase of 4d. per lb. on all tobacco was made, and an extra 2d. per lb. on cigars in 1879, with the result that after that date the consumption fell to 22½ oz. From this time it gradually recovered till in 1887, when, the duty on tobacco being reduced 4d. per lb. and on cigars 6d. per lb., the consumption quickly rose till it attained to 26 oz. per head of population in 1893. The total consumption in 1893 was 62,000,000 lb., while in 1861 it was 34,000,000 lb.—i.e., an increase of 28,000,000 lb. for an increase in the population of 10,000,000. To sum up, this interesting return shows that there is a decided diminution in the demand for intoxicating stimulants, whilst there is a very considerable increase in the demand for non-intoxicating stimulants, principally tea and coffee. There would appear therefore to be a distinct and steady reaction setting in against general alcoholic imbibition—a fact which lends support to the view that the evil of intemperate drinking, as its wretched consequences become more and more painfully manifest, will finally work out its own remedy. It is beginning to be recognised—if we interpret the return correctly—that the effect of alcohol is comparable to the flick of the whip, which for a brief period urges on the horse, while the rational use of tea and the allied beverages, of which theine is the base, is more like the corn out of which a more real and lasting energy is derived. It is idle to argue, however, that both sources of energy and stimulation have not their use as well as their abuse. Finally, the enormous increase in the amount of tobacco consumed is noteworthy, and would seem to indicate a growing demand for a substance which, when temperately indulged in, doubtless affords a source of comfort and relief to many in the increasing struggles and worries of modern existence.

CHITRAL.

CHITRAL is now in everybody's mouth, so that Captain Younghusband's paper, read on Monday last before the Royal Geographical Society, on that province, Hunza, and the Hindu Kush was a remarkably apposite contribution and was listened to with the deepest attention by a large audience. Captain Younghusband has only recently returned from official residence of more than two years in the primitive little States where the empires of India, Russia, and China touch, and he spoke of the country and its physical resources, and of the people, with their curious, savage, childish, pleasant temperaments, with the picturesque clearness that is born of intimate knowledge. To us as medical men no less than as subjects of the Empress of India the recent *émoué* at Chitral has a particular interest, for the British Agent, now immersed in the

Chitral fort, is Surgeon-Major Robertson, a member of our profession, and it is with a view of rescuing him from the attack of a usurping border chief that an expedition is to be sent up. No one who heard Captain Younghusband's address can fail to see that an expedition into such a country must be attended with the greatest risk to life. The roads are only tracks at the bottom of frightful mountain gorges or indications of a path—for no real paths exist—running sheer up the sides of pure rock. The mountains stand up twenty-five thousand feet into the air, and so abruptly that it is possible to see at a glance two-thirds of their enormous altitude. It follows from this geographical formation that any expedition sent through these passes must be easily susceptible of attack, as throughout their route their position would be always commanded by an enemy placed on higher ground. The military tactics of the mountains is to get and keep the higher ground, and the marching force would necessarily be almost always on the lower. Lord Roberts, in his excellent speech upon Captain Younghusband's paper, laid stress upon the strategical importance of Chitral and of a direct road from Peshawar to Chitral in the scheme of frontier defence, and expressed confidence that the well-organised and well-equipped force which Sir Robert Low will have under his command should reach its destination in safety. No one in the world is more qualified to express an opinion on such a subject than Lord Roberts, and his outspoken remarks are very reassuring. Let us hope also that the expedition will reach Chitral in time.

THE HIPPOCRATIC REVIVAL.

MEDICAL scholarship has been busy of late in clearing up the early progress of the healing art. Not only have we had such interesting monographs as those of Dr. Constantin Tsintsiropoulos on "La Médecine Grecque depuis Asclépiade jusqu'à Galen," and of M. Maurice Albert on "Les Médecins Grecs à Rome," but we have had critical recensions of such authors as Aëtius, whose twelfth book has been for the first time given to the world (*πρώτον νῦν ἐκδοθεῖς*) by that admirable Hellenist Dr. George A. Kostomoiros, Professor of Ophthalmic and Aural Medicine in the University of Athens. It is the Father of Medicine himself, however, that has received the largest share of attention; and, whether we take the admirable biography of him contributed by the late August Hirsch to the "Biographisches Lexikon der hervorragenden Aerzte aller Zeiten und Völker," or the masterly edition by Dr. Theodor Gomperz of the *Ἱερί Τεχνῆς* (or apology for the healing art) which is generally included in the Hippocratic collection, we have ground for congratulation on the fresh light thrown on the most commanding figure in medical history. Within the last few weeks we have had further evidence of the enthusiasm with which ancient medicine, and particularly its Hippocratic period, is being cultivated. Dr. Michel Sourlangas has recently presented us with an "Étude sur Hippocrate: son Œuvre, ses Idées sur l'Infection, et ses Moyens Antiseptiques," in which he puts in evidence the fact that "the great and glorious conquest of modern surgery, antisepsy, was not unknown to Hippocrates," who indeed "recommends it several times in his works and often in a way so precise 'que l'on se croirait en présence d'insinuations modernes.'" Prefixed to a useful appendix of Hippocratic maxims, in which the carefully revised Greek text is accompanied with a literal, yet flowing, translation into French, Dr. Sourlangas gives a summary of the conclusions reached in his monograph: first, that Hippocrates made medicine a science, and that on this ground he merits the title rather of Legislator than of Father of the Healing Art; secondly, that most of the infectious diseases were known to him—the rôle he attributes in their production to the air and the

water constituting in fact a scientific study in etiology; and thirdly, that he availed himself in treatment of substances whose virtues as microbicides are undeniable. But more important than these incidental excursions into the fascinating field of ancient medicine is the new German translation of the entire Hippocratic collection by Dr. Robert Fuchs, of which the first volume is now before us. In this the reader will readily discern that Dr. Fuchs is a more learned scholar than his predecessors, and that he has also the advantage of belonging to a sounder, more scientific medical school. The language in which he reclothes the Greek author is that of modern medicine, and the interpretation he gives is such as was possible only to one who has profited by the vast accessions to our knowledge of antiquity made by the archaeologist, the epigraphist, and the special investigator of antique life and culture. His familiarity with such monographs as the well-known "Die Botanik Homers" and such monumental treatises as that of Berendes on the "History of Pharmacy" (commented on in THE LANCET of April 2nd, 1892) will illustrate our meaning. The undoubted advantage he possesses over Littré, Adams, and Ermerins is also manifest in the notes, which from their richness in expository matter contribute to make this book an encyclopædia of Greek medicine. The first volume comprises the introductory writings of Hippocrates, then the general treatises, then that on Dietetics, and, finally, the general pathology and the prognostics. The second volume will include the special pathology and therapeutics, and will be ready next summer. The third, completing the work, will appear in September or October, and will deal with therapeutics (second part), surgery, ophthalmic medicine, gynaecology, treatment of infancy, and the Hippocratic correspondence. The entire publication will indicate the high-water mark attained by European research and scholarship in the "mare magnum" of Greek medicine, and our only regret in calling attention to it is that, since Francis Adams published his translation some fifty years ago for the Sydenham Society, British learning has done so little for a subject in which it has in past centuries shown its ability to excel.

THE DISCOVERY OF HELIUM.

THE earth spirit allows us to see more and more of the fabric that falls from his whirling loom, and we may, perhaps, soon be able to gather the scattered threads together and behold the full beauty of the great design. After the Faraday Medal had been presented to Lord Rayleigh at the annual meeting of the Chemical Society on Wednesday, the 27th inst., his co-worker in the discovery of argon, Professor Ramsay, was called upon to speak. He announced that in his endeavours to discover a compound of argon he had experimented with a rare earth—cleveite, we believe—which was said to yield nitrogen when acted upon by sulphuric acid. Instead of nitrogen, argon was evolved, but associated with it was some strange gas. On examination this turns out to be helium, the lightest of all the possible elements, whose existence, apart from the demands of chemical theory, had only been inferred from the line D₃ in the solar spectrum. It is the first of all the elements, for below this comes the hypothetical "protyle"—that pre-elementary cosmic stuff from which all the elements are supposed to have condensed. Although this small quantity of helium was only found a few days ago its existence has been confirmed by Professor Crookes, who has identified its spectrum, of which the most powerful line is that at a wave-length of 587.47 micro-millimetres. This line is almost identical with the well-known yellow Sodium lines, and at first Professor Crookes thought that he had to deal with these, but all the magnifying power at his disposal was incapable of separating the lines into two, and

careful measurement confirmed the suggestion that the line was no other than the D_3 line in the solar spectrum, attributed to an unknown element, provisionally termed helium. A more remarkable vindication of our chemical theories than this it would be difficult to find, and Dr. Ramsay is to be congratulated deeply on this fresh addition to our knowledge and to his own laurels.

THE HEALTH OF H.R.H. THE DUKE OF YORK.

THE Duke of York has been suffering during the past week or ten days from a mild attack of influenza, from which we are glad to be in a position to report authoritatively he is now rapidly convalescing.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.

MR. T. HOLMES, Hunterian Lecturer in Surgery, will deliver three lectures in the school in the month of June on the Experience of the Hospital in Abdominal Surgery (excluding gynaecological operations) from 1888 to 1894 inclusive. Dr. W. H. Dickinson, Baillie Lecturer in Physic, will deliver three lectures in the school in the same month: (1) on Some Points touching Valvular Disease; (2) on Some Recent Observations relating to the Cardio-Vascular Change of Renal Disease; and (3) on Dropsy. These lectures will all be public and members of the profession will be admitted on presenting their cards. The dates and hours will be announced later.

A DEGENERATE EXHIBITION.

IN a recent issue we drew attention to the folly, if not worse, of exhibiting patients in an hypnotic trance for the purpose of making money. Those experiments were bad enough, but we now hear of an intention to take a victim through England whilst in a trance. The first stay was to be at Cardiff (we quote from the *Evening Standard*), and doubtless crowds will flock to see the absorbing spectacle of a "slender, little, pale, nervous sort of man," apparently asleep. At Cardiff he is to stay six days, be awakened, re-hypnotised, and start for another town. Such pandering to a morbid taste is scandalous. The only possible attraction in such a show must be the idea or chance of something untoward happening; for it has not the excuse, like acrobatic performances, of being an exhibition of highly trained physical powers. In the event of a fatality occurring we hope that not only the showman but the gaping idiots who go to see the "man in a trance" will be compelled to pay a heavy penalty.

A SIX-DAY RECORD OF OPHTHALMIC SURGERY.

AS an evidence of the very large amount of ophthalmic work occasionally done in a village district of India we may place the following on record. A few weeks ago Surgeon-Lieutenant-Colonel G. C. Hall, F.R.C.S. Eng., surgeon to the Allahabad Eye Hospital, was called upon to operate on a patient in a village in the province of Oudh. The village was some twelve miles from the railway and twenty-six miles from any English station. No means were taken to let the people in the surrounding villages know of the intended visit of an ophthalmic surgeon to their neighbourhood, but the news nevertheless spread. Surgeon-Lieutenant-Colonel Hall lived in camp. The natives arrived in various ways—some in bullock carts, having been four or five days on the road, from distant villages; some came on foot, led by others not quite so blind as themselves; others were carried on the backs of their relatives. A large number had no eye left to be dealt with, but all had a large amount of faith. It was altogether an extraordinary and weird spectacle to see these poor, helpless people coming into camp in the early morning and quietly sitting down in groups patiently waiting until their turn came. During six days the total number of patients seen

was 394, the total number of cataracts extracted 69, and the total number of operations performed was 147. The operations were all done in the open air under the shade of a large mango tree, the patient lying on a native bed, the operator sitting at the head of it. As far as possible all the cases were treated antiseptically, and notes were taken of them with the prognosis formed at the time of operation. When Surgeon-Lieutenant-Colonel Hall left, which he did on the sixth day, a native assistant remained to look after the patients, to whom sixty-five pairs of spectacles have already been forwarded for the successful cases. We think our readers will concur with us in considering that the foregoing account records an enormous amount of hard and successful work of a most humane and philanthropic kind, of the accomplishment of which anyone may well feel proud.

THE PRESERVATION OF HEALTH IN THE FAR EAST.

OUR attention has been called to a useful pamphlet issued under the direction of the Medical Mission Committee of the Church Missionary Society for the guidance of its missionaries in China and published by the Church Missionary Society. This little guide to health has been compiled by W. P. Mears, M.A., M.D., late of the Fuh-Kien Mission, and it gives some excellent hints as to clothing, food, and residence in China. The members of the Church Missionary Society are necessarily scattered about abroad, many of them must live in isolated stations among semi-civilised people and remote from medical aid, and something in the way of a guide of this kind therefore seems to be very necessary, if not essential. The pamphlet is chiefly concerned with matters connected with travel and residence in Mid- and South-China, but it affords many very practical and useful observations for those proceeding to Eastern climates. The hints as to the personal, travelling, and general outfits required, and the remarks about the site and construction of a house, with its lighting, ventilation, drainage, and water-supply, strike us as very good on the whole. The work, it should be added, is illustrated with several excellent plans and diagrams.

ASEPSIS AND ANTISEPSIS IN OBSTETRIC PRACTICE.

THE January number of the *Annales de Gynécologie et d'Obstétrique* contains an interesting article on Professor Tarnier's work entitled "De l'Asepsie et de l'Antiseptie en Obstétrique." The earliest contribution to a determination of the nature of puerperal fever is credited to an English medical man, White, who towards the middle of the last century formulated the opinion that puerperal fever could be contagious. His views, however, seem to have met with no support. In 1846 Kneeland published a summary of the opinion of certain English and American physicians, which seems to have been very near the truth, since he insisted not only that puerperal fever was contagious, but that it might be conveyed by infected bedding &c. and by medical men, and especially if they had recently made necropsies on those who had died from puerperal fever. Still, it was not till Semmelweis, in 1847, was struck by the difference in the mortality among those who were attended by students who were working at the same time in the dissecting-room and in the class of operative surgery, and the mortality among the lying-in patients attended by midwives, that the true causation of puerperal fever was in a fair way to be ascertained. The antiseptic era as regards midwifery undoubtedly dates from 1847. Professor Tarnier recalls how when he was an in-door pupil at the lying-in hospital between May 1st and 10th thirty-two women were delivered, and that thirty-one died. He questioned his

teachers on the subject, and they told him that the epidemic was equally prevalent among lying-in women in the town, and that such a state of things "always had been so, and always would be so." Not content with this answer, and unaware of the work of Kneeland and Semmelweis, he investigated the point for himself, with the result that he found the mortality among lying-in women in the hospital was seventeen times greater than among those in private practice. This convinced him that puerperal fever was contagious. The researches of Coze and Feltz, of Pasteur, of Doléris, of Chauveau, and of Vidal, by which the part played by micro-organisms was investigated, are referred to; and those that accoucheurs should more especially fear are stated to be the streptococcus pyogenes, the staphylococcus aureus, and the septic vibrio. The most interesting question from the practical point of view is as to the course of procedure needed to apply the antiseptic principle in attending lying-in women. Much valuable information is given by Professor Tarnier on this point. A list is given of the principal antiseptics in the order of their activity. Among those in common use here we find that the perchloride of mercury, free iodine, carbolic acid, and permanganate of potassium are respectively first, third, fifth, and seventh on the list. The measures needed to render the hands aseptic are given in much detail. The importance of keeping the nails short is insisted on. We see, however, that in the preliminary washing of the hands with soap and water and a nail brush it is recommended to have sublimate in the water, although it will be to a greater or less extent decomposed when so used. It is true that a final washing of the hands in sublimate solution, without soap, is also advised. We think that it is a good rule, after thoroughly washing in soap and water with a nail brush and getting rid of the soap, not only to soak the hands in the sublimate solution, but to thoroughly brush both the hands and nails with the same solution. We see that Professor Tarnier thinks that iodine water is the best antiseptic to choose for intra-uterine injections, and he considers that it has a special property of penetrating some distance into the thickness of the tissues. He considers sublimate lotion too dangerous for use within the uterus, unless followed by an intra-uterine injection of some inert fluid, which, of course, weakens its antiseptic action. Sublimate lotion for the hands, carbolic lotion for the instruments, and iodine water for the uterus appears to be a good arrangement for actual practice.

THE SUPERVISION OF PULMONARY TUBERCULOSIS IN NEW YORK CITY.

A RECENT number of the *American Journal of the Medical Sciences* contains an interesting account by Drs. Herman Biggs and J. J. Huddleston of the sanitary supervision of tuberculosis as practised by the New York City Board of Health. The account is one which medical officers of health interested in the control of tuberculosis will do well to read, if only to bring home to them the difficulties which beset all attempts to do this work with the thoroughness demanded by those who maintain that this disease is largely propagated by contagion. As early as 1889 steps seem to have been taken by the New York City Board of Health towards educating the public as to the nature of tubercle by means of the distribution of leaflets &c.; and in the beginning of 1894 it was resolved to take action with a view of preventing the spread of the disease. Briefly put, the steps taken resolve themselves into the registration of every person suffering from tuberculosis, in so far at least as information can be obtained by compulsory notification from public institutions and voluntary notification from private practitioners; the control by specially appointed medical inspectors of cases residing in tenement houses,

boarding-houses, or hotels where such cases are not already under the care of private practitioners who have notified their willingness to give all the necessary instructions; the renovation of premises and the removal of carpets &c. in cases where it is considered desirable by the inspectors, and in affixing to an apartment previously occupied by a tuberculous patient a placard setting forth the fact that no further occupation is to take place until the premises have been renovated and cleaned to the satisfaction of the Board. Furthermore, the bacteriological examination of suspicious tuberculous sputum is undertaken by the Board of Health. As may be imagined, regulations such as those indicated above are not carried into effect without some difficulty, and we are not surprised to hear that "as yet private practitioners do not generally report their cases of tuberculosis." False addresses are, we are told, frequently given, and occasionally wrong diagnoses are made. In the death certificates, too, pneumonia and chronic bronchitis are recorded as the cause of death when it is considered expedient to avoid the word tuberculosis. These false certificates are given, it appears, in some cases owing to the fact that by the regulations of many industrial insurance companies death from tuberculosis renders the life policy wholly or partially void. Drs. Herman Biggs and Huddleston state that, although the number of apparent deaths from tuberculosis has been falling for some years, in 1894 a much greater diminution took place than was ever the case before. When, however, we have regard to the uncertain period of incubation of tuberculosis and to the duration of the disease, we are tempted to wonder whether this marked diminution in so short a period is due to the dislike on the part of the public to "renovations" and restrictions imposed or to the good effects of the measures taken. Obviously, however, it is too early to judge what may be the result of the energetic action taken by the New York City Board of Health, and we shall look forward with very considerable interest to subsequent reports on what may be regarded as a bold experiment in sanitary regulation.

THE DIFFUSION OF SMALL-POX.

THE news coming to hand from the several places wherein small-pox still finds record is of a generally very reassuring character. The data for London, it is true, show a rise in each of the past two weeks as compared with a like earlier period, the numbers for the two weeks ended the 23rd inst. having been respectively 12 and 15, as compared with 8 and 8. In the week still earlier there were 19 cases, mainly owing to recrudescence in Marylebone Parish, in which parish Mr. Wynter Blyth states, in a report just issued, that in February 39 attacks were notified and removed to hospital, the 5 fatal attacks being all in young unvaccinated children. Of the 15 cases arising in London last week 14 were removed to hospital, the institutions of the Metropolitan Asylums Board and Highgate Small-pox Hospital containing at the close of last week 58 patients, against 68, 56, and 57 on the three Saturdays preceding. One death of an unvaccinated child occurred in the week before last, the deceased belonging to St. Marylebone Parish. Thus, it is seen that small-pox still clings to the metropolis, although it seems unable to fasten on the sanitary areas in an epidemic form. The suburban districts have been fairly free from the disease during the fortnight in question; but we learn that the town of Bedford has been freshly invaded, though the number of attacks has been small, amounting to some half-dozen in all. Derby appears to have got its outbreak in hand, and to be in a fair way to exterminate the disease, though 1 death was registered last week. Liverpool and the neighbourhood have had only an odd case or two to record, 1 death being registered in the city last week. Neither Edinburgh nor Glasgow has been free from fatal small-pox in the present month. Over the Channel matters

seem to be on the mend somewhat in Dublin, though still far from satisfactory. The admissions to hospital have during the several weeks of the present year shown an almost continuous disposition to decline in number, those for the seven weeks ended March 16th having been respectively 69, 60, 56, 37, 31, 34, and 30. In the week last named there were 4 deaths registered, all in unvaccinated individuals, aged two months, one, seven, and forty-seven years. In the preceding week there were 5 deaths, 2 of vaccinated adults, aged twenty and thirty-eight years, and 3 of unvaccinated persons, aged twenty-two days, thirty-six and eighty-three years. The numbers of patients remaining in hospital in the four weeks ended March 16th fell week by week from 135 to 110, thence to 93, and finally to 72; there are, however, 118 convalescent patients at Kilmainham.

THE CRAIG COLONY FOR EPILEPTICS, NEW YORK.

THE colonisation of epileptics, which has been commenced on a small scale in this country at Chalfont and Godalming under the management of two charitable societies, is about to be carried out on a much larger scale in New York and administered by the State. An estate of 1850 acres—formerly a colony of the Shaker community—on which there are already sufficient buildings to accommodate a number of colonists, has been purchased for £23 000. The salaries of officers of the colony are to amount to £2000; 100 of the inmates are to be “indigent persons” supported by the State, just as at our own colonies a certain number of the inmates are boarded out by the boards of guardians. The system of colonisation is to be that introduced at the famous colony at Bielefeld, in Germany, and adopted at the Chalfont colony, of lodging the colonists in small numbers in pleasant cottages with cheerful surroundings. The superintendent of the colony is to be a medical man, and he will be the supreme authority on matters of discipline and conduct as well as medical adviser to the colonists.

THE PREVALENCE OF DENTAL CARIES.

THE great prevalence of caries of the teeth nowadays, as compared with the past, is a subject worthy of much consideration, for sound teeth are an important factor in the maintenance of health. To what is this alarming increase of dental caries due? A degeneration in structure no doubt plays a prominent part, and this imperfection is to be found not only in the hard tissues of the tooth, but also in the alveolo-dental membrane, as evidenced by the frequent occurrence of premature loss of the teeth, a condition insufficiently recognised and one quite as important as the prevalence of decay. From time to time various theories more or less plausible have been brought forward to account for this degeneration in structure, but the only one which seems to explain the condition in a rational way is that advanced by Mr. Smith Turner in his presidential address to the British Dental Association in 1891, in which he considers that the various changed conditions of childhood—such as diet, education, amusements—operating together rob the body as a whole, and the teeth especially, of the earthy salts which are so necessary during the period of development. Fortunately the public is awakening to the fact that careful periodic attention to the teeth is essential, but not infrequently the visit to the dental surgeon is delayed until too late. A fallacious idea is prevalent among many parents that the temporary teeth do not require attention and the child is probably not seen by a dentist until perhaps ten or twelve years of age. By this time the most important teeth in the head—namely, the first permanent molars—have been erupted over four years and are quite possibly in a hopeless condition. If the great amount of caries of the present day is to be combated at all successfully the periodic visits to the

dental surgeon should start immediately after the completion of the temporary dentition. Too much stress cannot be laid on this point, and it is here that the medical practitioner can do so much by directing the parents' attention to the fact.

BATHS IN THE TREATMENT OF DISEASES OF THE CIRCULATORY SYSTEM.

IN our issue of last week we printed a necessarily condensed report of the meeting at Berlin of German balneologists. This week we publish a paper by Dr. Groedel of Nauheim upon the bath treatment in use at that watering place for diseases of the circulatory system. It will be remembered that Dr. Bezly Thorne contributed an article on the method of Schott with a number of cases to our columns.¹ The present paper gives an account of the technique of the baths, which may be useful to our readers.

LOCUSTS IN CYPRUS.

A RECENTLY issued Parliamentary paper gives some interesting particulars on the subject of the repression of locusts in this island. It has come to be considered that the trapping and burning of the insects practised for some years past are unsatisfactory, and reliance is now placed on the collection of eggs during the summer and winter, and of living locusts in the springtime. Labourers were not hired for the work, but the eggs and the living locusts were purchased from the villagers by weight. For egg-cases the price was sixteen piastres the oke, representing about 2600 egg-cases, and as each case contains thirty-two eggs, assuming that only one-half of these hatch out, 2600 locusts are secured for one piastre, equal to about twopence. The living locusts were caught either by driving them on to sheets laid on the ground or by scooping them up in muslin bags. Chickens could not be induced to eat the young insects. During 1894 the sum of £4302 was expended in combating these pests. The Jewish colonists whom, according to the *Gaulois*, Baron Hirsch would like to establish in Cyprus will obviously not find it to be a land flowing with milk and honey; but, as the Chancellor of the Exchequer has recently said, it is a pity that only half of the income of the island has been available for purposes of development. It would seem under these circumstances not quite fair to condemn it as *damnosa hereditas*.

THE BUCKS COUNTY COUNCIL.

WE referred in THE LANCET of March 16th to the fact that one of the results of the last Bucks Sanitary Conference had been to prolong the life of the county council sanitary committee, which at the time of the conference was in a somewhat precarious condition. Unfortunately the respite has been but a brief one, and we understand that at a meeting of the council, held on March 18th, it was decided by 23 votes against 19 to dispense for the future with the services of a sanitary committee. It is difficult to understand the exact meaning of this step on the part of the county council, as we can hardly believe that they propose to disregard their now by no means nominal duties in respect to the public health of their district. At the same time we fail to see how the powers of the council under the Local Government Acts, 1883 and 1894, the Rivers' Pollution, the Housing of the Working Classes, and the Isolation Hospital Acts can be properly exercised, if indeed they can be exercised at all, without the assistance of a sanitary committee. Indeed, we fear that any attempts on the part of the whole council to deal with the preliminary investigations and details in reference to complaints from parish councils &c. must, by virtue of the undue publicity which such a course necessitates, lead to a great resentment

¹ THE LANCET, May 5th, 1894.

on the part of the local sanitary authorities. Schemes and complaints brought before the council should surely be presented in a well-digested and easily assimilable form, and not in such condition as to require detailed discussion. That the Bucks County Council should have considered a sanitary committee necessary before the passing of the Local Government Bill, 1894, but not afterwards, appears to us to be a somewhat strange recognition and appreciation of their increased responsibilities. We should have imagined that increased duties required a more complex machinery.

THE HEALTH OF LORD ROSEBERY.

WE are very glad to be in a position to announce that Lord Rosebery has made decided progress during the week. His sleep has been of better quality, and he has as a consequence gained strength. He has remained at Epsom, his detention there having been partly determined by the exigencies of public business and partly by his own private preference. He has felt the improvement that has taken place in his health during his sojourn there, and has not been eager to go away for a change. Nor did his physicians wish him to do so until the severity of his insomnia had abated.

THE MIDWIVES BILL.

A DRAFT form of a Bill for the Registration of Midwives has been forwarded to us on the lines indicated in previous Bills of the sort. Those in *bonâ-fide* practice or who have obtained a certificate in some hospital or workhouse infirmary and who claim to be registered within one year from the passing of the Act will be entitled to be registered. Thereafter admission to the register will be the privilege of those who pass the examination of examiners nominated by the Midwives Board but appointed by the General Medical Council. The Council is expected also to frame rules regulating the conditions of admission to the examination and the practice of midwives. The Bill will require much criticism, for which in the present state of Imperial and medical politics there seems to be likely to be ample time.

MATTHEW HOPKINS REDIVIVUS.

It is curious to notice how, after twenty years of School Boards and a great many other means of spreading education, superstition and savagery still linger in various places. Only the other day a farmer near Ilfracombe, whose cattle were attacked with anthrax, went to consult a "white witch" at Exeter, who informed him that the cattle had been "overlooked." He took no measures to prevent the spread of infection and is reported to be ruined. This instance, though bad enough, is as nothing to the appalling tale reported from Ireland. An unfortunate woman named Cleary was suffering from bronchitis, and some of her "friends" conceived the idea that she had been spirited away and a witch substituted. They accordingly called in a "herb doctor," who administered some potion, while the husband adjured her in the name of God to say that she was not his wife. As a means of accelerating her comprehension she was held over the fire. The next night the proceedings were repeated, and in addition she was drenched with paraffin oil and placed on a fire. As she burned more oil was thrown over her. The charred body was then hidden in a ditch. While she was burning the relatives and the "herb doctor" stood round expecting to see her fly up the chimney. As the case is now *sub judice* we cannot comment further on what will be the result; but it may well give us cause for reflection that such crass ignorance is still possible. The witch mania was perhaps the most terrible form of insanity, for it was an insanity, that ever afflicted the human race. As far as we know, neither Buddhists nor Mohammedans have

been attacked by it, but the records of the Roman and Anglican Churches are full of burnings and torturings, while among Protestant bodies Cotton Mather in America and many an official in Germany made "perambulations" for the discovery of witchcraft. The curious in such matters will find an interesting account thereof in Meinhold's "Amber Witch."

"DEPRIVATION OF DEGREES."

A PAMPHLET sent to us, entitled "The Private Medical Adviser, by Dr. Fraser, M.B., C.M., on Nervous Debility, its Causes, Consequences, and Private Treatment," would appear to be a flagrant illustration of the absurd inability of the universities to deal with medical graduates who abuse their position by publishing pamphlets on private and delicate subjects, conceived in the worst style of the quack who lives on the most pitiable weaknesses of his fellow creatures. The person in question is, it is admitted, a graduate of the University of Aberdeen. The University will be quickened in its efforts to acquire powers for dealing with such graduates by the creditable action of other universities—notably, Cambridge, Durham, and Wales. In the drafting of the charter of the new University of Wales, as Dr. Isambard Owen informs us in another column, the point is to some extent provided for, and power is given to the University to revoke its degrees for sufficient cause. The section in the charter of the University of Wales does not, however, go far enough. There are many offences for which a university might desire to punish its graduates by depriving them of their degree which are not felonies or indictable misdemeanours.

DIPHTHERIA IN LONDON.

DIPHTHERIA in London has in the past two weeks shown sensible decline in its fatal form. Having fallen from successive weekly numbers of registered deaths of 31 and 34 to 27 in the week ended March 16th it showed further decline last week to 24; and whilst in the preceding week the deaths were 5 below the corrected average, they were last week also below the average—namely, by 4. All in the first week of the fortnight, and 23 in the second week, were in persons aged under twenty years. Of the total 51 deaths, the Registrar-General credits Camberwell and Greenwich each with 6, Lambeth and Mile End Old Town each with 3, and 2 each occurred in Fulham, Kensington, St. Martin-in-the-Fields, and Battersea sanitary areas. During the four weeks including the fortnight with which we are dealing the admissions have been constantly growing in regard of hospital treated cases, the number having been respectively 43, 55, 61, and 64; and last Saturday found 455 patients still under treatment, as compared with preceding week-end totals of 463, 455, and 456. In this way it is seen that the disease is for the time maintaining itself in London, but shows no disposition to increase. In its fatal form especially the evidence is rather in the contrary direction. In Greater London there were in the two weeks 15 deaths registered from diphtheria, of which 9 were in West Ham, 2 in Croydon, and 2 in Romford districts.

THE DENTISTS' REGISTER FOR 1895.

PREVIOUSLY to the passing of the Dentists Act in 1878 anyone arming himself with an instrument serving as dental forceps, and presuming on the lethargy of the public, could set up as a dentist; but after the passing of this Act anyone who took the title of "dentist" or any title implying registration unless registered under the Act was liable to a penalty not exceeding £20. Despite, too, the fact that a false declaration rendered the maker thereof liable to one year's imprisonment, the publication of the first Register showed that 4806 persons embracing various

trades, not excluding the gentle craft of the blacksmith, had claimed the right to be on the Register. Many of these, of course, possessed no qualification whatever, but time must necessarily erase their names from the roll. At the present time the total number on the Register is 4901, including 27 gentlemen who possess the dental qualifications of Harvard or Michigan Universities, U.S.A. These qualifications are not yet recognised by the General Medical Council, and these gentlemen are designated in the Register "Foreign Dentists." Slowly, yet surely, the number of Licentiates in Dental Surgery of the various Royal Colleges of the United Kingdom is increasing, while the number of those whose names are upon the Register by virtue of their being in practice before the passing of the Act is decreasing. The proportion of the former to the total number on the Register is 27·82 as compared with a percentage of 26·48 in 1894. Of the latter class who do not possess qualifications the proportion is 70·98 as compared with 72·35 last year. On deducting the 27 foreign dentists from the total number on the Register and comparing the remainder with last year's figures it will be seen that there is an addition of 79 names.

PUERPERAL POLYNEURITIS.

DR. LUNZ of Warsaw has recorded in a recent number of the *Deutsche Medicinische Wochenschrift* an interesting case of this rare and peculiar condition, in which the symptoms differed considerably from those usually recognised. In the usual form there is an isolated neuritis of the upper or lower extremities, while the case here mentioned resembles more closely post-diphtheritic paralysis, inasmuch as difficulty in swallowing and diplopia were present, and also what is rare in diphtheritic paralysis, an affection of the face. With regard to the etiology of the condition it does not seem to follow only a pathological puerperium. Dr. Lunz believes that cases can be divided into three groups: a pyæmic or septic group, in which the neuritis follows some local infection; a cachectic form, which succeeds grave disturbance of nutrition, such as may be produced by loss of blood, persistent vomiting, &c.; and a third group, in which neither infection nor cachexia can be regarded as the cause, but in which the psychical disturbance which the confinement produces is to be regarded as determining the onset, just as it probably does of the puerperal psychoses which occur without puerperal infection. He urges, in conclusion, that obstetricians and psychologists should coöperate to elucidate the obscurities of these important and little understood conditions.

THE RECENT GALE.

THE gale of Sunday, March 24th, was remarkable in many ways. It was extremely destructive within the district where it was felt, but that district was remarkably circumscribed. According to the *Times*, if we take a triangle formed by joining the points of Valentia, the mouth of the Thames, and Scarborough we shall pretty accurately map out the affected region. Within this area the wind worked terrible destruction, and the accounts of the damage done to buildings and trees recall those of the great storm of 1703, when Winstanley, over-confident in the stability of his newly built Eddystone Lighthouse, hoped "that God would send the greatest storm that ever blew out of Heaven," and, as a contemporary writer remarked, "God took him at his word." Perhaps the most distressing feature of the recent storm was the number of hospitals that were demolished. At Walsall two wards in the district hospital were completely wrecked, in one of which the floor, a nurse, and eight female patients collapsed into the board-room below, but all were apparently unhurt. More disastrous were the results in the other ward, where the roof fell in and buried the patients. One man had both legs fractured and otherwise

badly cut. At Grimsby a chimney crashed through the roof of the children's ward in the hospital, burying a child aged six years, who died an hour afterwards. At Hinckley, in Leicestershire, the isolation hospital, in which were nineteen patients suffering from diphtheria, was completely destroyed. Fortunately, warning was given by the wrecking of the out-buildings, and the patients were carried out wrapped in blankets and laid under a hedge. A word of praise is due to Mr. Goode, who offered his house as a temporary shelter. Compared with tropical hurricanes, our record of disaster is perhaps light, but for all that we fear that widespread distress has been caused.

MENTAL DISTURBANCE FROM IODOFORM.

IN the *Neurologisches Centralblatt* there is the abstract of a curious case recorded by Dr. Oldenburg. A female patient aged fifty-one, who had suffered from epileptic attacks from the age of twenty, but in the intervals between the attacks had been quite healthy and not psychically peculiar, injured her hand in a fit and was treated with a 10 per cent. iodoform ointment. Twelve days later she became excitable, restless, and confused, and by-and-by had hallucinations. The urine gave a distinct iodine reaction. When admitted to hospital she talked incessantly, would not answer questions, could scarcely be kept in bed, and complained of plots and persecution. The restlessness increased, and the patient became cyanotic; the urine contained albumen, but gave a very slight iodine reaction. She then remained quiet for a few days, but became again demented, after which she had another period of quietude followed by another outbreak, which, however, subsided, so that she was then able to be discharged. Dr. Oldenburg thinks the condition cannot be regarded as a post-epileptic mental disturbance, because of the interval that elapsed between the last attack and the onset of mental symptoms. He thinks it was determined by the iodoform poisoning acting upon a nervous system predisposed by epilepsy to grave disturbance.

THE LIQUEFACTION OF HYDROGEN ACCOMPLISHED.

UNDER the combined influences of great pressure and intense cold, hydrogen has at last surrendered and been liquefied. The means by which this has been effected have, of course, been at the disposal of the physicist and chemist for many years, but Professor Olszewski of Cracow, who, it may be remembered, also liquefied argon and examined its properties, has been the first to succeed in obtaining liquid hydrogen in tolerable quantity, since he has been able, we learn, to give two constants in regard to it. Thus it is announced that its critical point—the temperature at which it passes from a liquid to the condition of vapour—is -233°C ., and its boiling point at normal pressure is -243°C . It is well known that hydrogen has hitherto most strenuously resisted all attempts at liquefaction, and the fact of its obduracy in this respect, though in other respects it is most tractable, having now been overcome, removes the only gaseous element known to us which has not been liquefied. Until, therefore, more attenuated gases even than hydrogen are added to the list of chemical simplicities no further discoveries on this particular line of research can be hoped for. Meanwhile a detailed communication from Professor Olszewski on his very important discovery, which has just been announced, will be awaited with keen interest.

It has been decided by the Abernethian Society of St. Bartholomew's Hospital to hold a *conversazione* in the Great Hall of the Hospital and in the Medical School buildings to celebrate the centenary of the Abernethian Society on May 1st, 1895. Any past members of the society who desire

to be present on the occasion should communicate with the secretaries of the Abernethian Society before April 15th. A card of admission will be sent to those who apply, together with a ticket for one friend if desired. The number of tickets issued will be limited.

THE Erasmus Wilson Lectures on Pathology at the Royal College of Surgeons of England will be delivered by Mr. J. H. Targett, as already announced, on Monday, Wednesday, and Friday next, at the College, at 5 p.m. Mr. Targett has selected for his subject "Certain Forms of Neuropathic Joint Disease."

THE publication of the report of the Royal Commission on Opium is now imminent. The only dissentient to the opinion that both the cultivation of opium and the tax upon it should be maintained is understood to be Mr. Wilson.

THE REPORT OF THE SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA FOR 1893.

THE appearance of this bulky volume is looked for with interest in India and by all those who are concerned with the public health and vital statistics of that country. It is a sort of official health handbook of India of a big and ambitious kind. It deals with the diseases of the European and native armies, the gaoles and civil populations of India, with the epidemics that have prevailed during the year, and in addition to affording a vast amount of information embodied in a number of voluminous tables of all kinds has an appendix in which health problems and questions of a special and scientific kind are discussed. It cannot be denied that these reports are very laborious and valuable productions, of interest alike to the politician, the statesman and military department of India, and the medical statistic; but able as they are do they not attempt too much? It is impossible, as it appears to us, to deal adequately with such colossal materials and figures as the civil and military populations of such a vast country as India and its disease-causes in any one volume. To begin with the European army. The strength of that force serving in India in 1893 was over 70,000; the ratios per 1000 respectively were as follows: admissions into hospital, 1415; constantly sick, 87; deaths, 12.61; invaliding, 25; total loss, 38. The death-rate (12.61) seems to have been the lowest recorded for a number of years and was much under that for 1892, when it stood at 17.07 per 1000; the admissions were also less; and the health of the British army in India may therefore be said to have been better in those respects in 1893 than in 1892. Among the chief causes of admission were venereal diseases and ague. The increase in the former was very considerable; there were no less than 32,663 admissions for venereal disease, or 466 per 1000, against 410 in 1892. The admission-rate for cholera fell from 2.5 to 0.2 per 1000, and that for influenza from 12.7 to 0.3. Venereal diseases caused 33 per cent. of the total sickness, and ague 26 per cent.

The chief causes of mortality were enteric fever, pneumonia and pulmonary tubercle, dysentery, and injuries. Enteric fever caused 42 per cent. of the total deaths, and injuries 8 per cent. There was a marked increase of sickness amongst the European troops stationed at Quetta. The admissions for ague at that station were more than doubled. The health of the troops in Burmah has improved steadily since 1889, but the improvement in respect of sickness from malarial fever is almost counterbalanced, we are told, by increased prevalence of venereal disease. The admissions from this cause in 1893 amounted to 503.1 per mille. Enteric fever is much more prevalent in Bengal than in either Madras or Bombay; so also is remittent fever. On the other hand, simple continued fever appears to be more prevalent in Madras than in Bombay and Bengal, and the same remark applies to dysentery. In all three Presidencies enteric fever causes the largest number of deaths; next to it, and in all the Presidencies, comes hepatic abscess. The percentage respectively

of enteric fever, hepatitis, dysentery, and pneumonia in the total deaths of each Presidency in 1893 was:—

	Bengal.	Madras.	Bombay.
Enteric fever	44.6	35.2	36.5
Hepatitis and hepatic abscess	7.0	11.7	5.1
Dysentery	3.4	6.2	5.1
Pneumonia	6.5	2.3	4.4

It may be remarked here that the prevalence and mortality from pneumonia are much greater amongst the native army than amongst the European troops: about 4 deaths among the former to 1 of the latter. Moreover, although dysentery affects European and native troops almost equally there is a marked difference in their liability to abscess of the liver; the admissions from this cause amongst the former were thirteen times more numerous, for equal strengths, than among the latter, and the mortality was twelve times greater. As regards enteric fever, we know that the liability of the European soldier to that fever, as compared with the native, is enormously greater, but we shall revert to this point later on. The foregoing facts are noteworthy, however, and open up, as it seems to us, a field for useful investigation.

As regards cholera there were only 16 cases throughout the European army in India in 1893 with 10 deaths; 9 of the cases occurred in Bengal, 6 in Bombay, and 1 in Madras. Of the Bengal cases 4 occurred at Umballa, and were, in the opinion of the medical officer, due to importation from a gang of infected coolies working on the Simla road in April; but as it was not known that the coolies ever entered Umballa, and no sort of communication, direct or indirect, was traced, this hypothesis is deemed untenable, especially as it is a fact that in years of epidemic cholera April and May are precisely the months for the disease to make its appearance in Umballa. There were also 3 fatal cases at Meeran Meer. They all occurred within thirty-six hours, on May 3rd and 4th. Two of them belonged to one regiment, but to different companies, while the third occurred at a distance of two miles from the others. The hypothesis that the disease was conveyed in this instance by either soda water or drinking water, which was urged, seems to be contradicted by the fact that the disease only lasted two days and affected only three men, one of whom lived at a distance of two miles from the others. Whilst on this subject we may repeat what we have said long ago, that we have no confidence in barrack filters. They are, under the circumstances and conditions of military life in cantonments, probably rather a source of risk and danger than a protection to health against pathogenetic micro-organisms. The reliable and proper plan is to provide a perfectly pure and good water-supply at its source, and to see that it is kept so and protected from all contamination until it reaches the individuals drinking it.

(To be concluded.)

ALDRESHOT: THE SANITARY AND SOCIAL CONDITIONS.

(Concluded from p. 772.)

WE dealt last week with the question of the drainage of Aldershot; the disposal of sewage is, however, not the only difficulty to be surmounted there. The presence of the camp has brought about social conditions that are the cause of much embarrassment to the civil authorities. The camp indirectly causes a considerable increase of pauperism, with which the civil authorities have to deal. For instance, a large number of military pensioners have elected to live at Aldershot. These pensioners are paid every three months. This mode of payment is a very serious mistake. A great good would be effected if the military authorities could arrange to pay the pensions in weekly instalments—through, for instance, the agency of the post office. The necessity of a reform in this direction has made itself heavily felt at Aldershot. The old soldiers, having received their quarterly allowance, to use their own expression, "lived like lords" for a week or two; then, when all their resources were exhausted, came upon the union and lived at the ratepayers'

expense for the rest of the quarter. This was so crying a grievance that special regulations had to be made by which the workhouse authorities got a charge on the pensions of those pensioners whom they had relieved.

Though the difficulty caused by the pensioners has thus been settled, nothing as yet has been done with regard to the grave problem involved by the presence of a large number of women whom soldiers have married without obtaining leave. These women usually follow their husbands about from garrison to garrison; but at Aldershot the soldiers are prepared for foreign service, and it is impossible for these women to follow their husbands to Gibraltar, Malta, India, &c. Thus it is at Aldershot that the separation between man and wife very generally takes place. What becomes of these unfortunate women when their husbands have gone? It is not in a small town of only 14 000 inhabitants that they can readily find employment. Some may obtain a little washing to do either for the women in the married quarters or for the officers' families; probably the greater number are driven to prostitution. Some of them become so extremely poor that they reach the very lowest strata of fallen women. Their poverty is such that they have been known to sleep in the open air, and offences against decency are often committed under the shelter of trees, embankments, furze, and other covering. As there is no law whatsoever to regulate the conduct of these women, to bring them under treatment when ill, to teach them cleanliness, and to put them in connexion with those institutions that would help them to a better mode of life, syphilis and other contagious diseases are of course very prevalent at Aldershot. This is a vexed question, and there has been much juggling with figures; but in any case, so far as Aldershot is concerned, the last Army Medical Department Report for the year 1893 confirms the opinion just expressed that the grievance is especially acute at Aldershot. Taking all forms of venereal disease together for the United Kingdom, the total admission ratio per 1000 was 194.6, and the constantly-sick rate 16.68, and these compared with the average of the last seven years show a decrease in the former of 29.0 and in the latter of 0.79. As compared with the previous year, the decrease in admissions is 6.6 per 1000, whereas at Aldershot, instead of a decrease there is an increase of admissions equal to 36.9 per 1000.

If we take the figures during the last few years the Contagious Diseases Act was in force we find that the ratio of admissions for venereal diseases at Aldershot was in 1878 138.36; in 1879, 163.35; in 1880, 197.78; in 1881, 211.58; and in 1882, 261.13 per 1000. How far this notable increase of figures is due to the less strict application of the Act at a time when it was about to be abolished or to the arrival of a specially large number of recruits it was difficult to ascertain. With regard to the recent figures, these were not altogether easy to obtain and seemed rather low. Under the heading "venereal diseases" the ratio for the last three years was 252.3, 210.3, and 156.6 per 1000; but this did not include ulcers of the penis and balanitis. Adding these complaints, the figures were apparently 260.03, 221.3, and 189.8 for the years 1890-91, 1891-92 and 1892-93. As there has been an increase of 30.9 for 1893 the figure for that year would show that 226.7 soldiers out of every 1000 soldiers quartered at Aldershot were admitted during the course of the year for all forms of venereal disease.

Considering the great fluctuation that must ever take place in such diseases it will be seen that there is no very marked difference in the prevalence of venereal disease before and after the Contagious Diseases Act was abolished. But then it must be borne in mind that these figures include gonorrhoea, which the Act does not help to check. The utility of such legislation is best set forth when the prevalence of secondary syphilis, about which there can be no mistake, is studied. Thus, in 1893 the rate of admission into hospital for secondary syphilis was in the United Kingdom equal to 31.8 per 1000, and the constantly-sick rate 3.31. The figures for England and Wales stood higher—namely, 37.4 and 3.74; and the average for the last seven years in England and Wales was 39.5, and 3.66 constantly sick. If, on the other hand, we take the island of Malta, where a Contagious Diseases Act is in force, the ratio per 1000 of admissions for secondary syphilis in 1893 was only 13.3, and the constantly-sick rate only 1.69. The average at Malta from 1886 to 1892 of cases of secondary syphilis is 14.6 per 1000 per annum, and the constantly sick 1.42. Thus, roughly and to put the case in round figures, we may say that for three soldiers who suffer from secondary syphilis in the United Kingdom, where there is no Contagious

Diseases Act in force, only one soldier suffers from secondary syphilis in the island of Malta, where a Contagious Diseases Act is in force. With regard to all classes of venereal diseases the statistics for Malta do not present the same startling difference, but they are more favourable than the home returns. For 1893, instead of 194 admissions to hospital and 16.68 constantly sick, the figures for the United Kingdom, there were at Malta 122.3 admissions and 10.56 constantly sick; and these latter figures are above the average. From 1886 to 1892 the average at Malta was 91.6 admissions to hospital and 7.39 constantly sick for all venereal diseases per 1000 men per annum.

In dealing with this question we must not only look at figures. Above all, we must consider social conditions. These, fortunately, have greatly improved. First and foremost, the army is composed of a much higher class of men than was the case some twelve and more years ago when the Contagious Diseases Act was in full force. The School Board has had time to produce a change for the better, and there is now a fair sprinkling of gentlemen serving in the ranks. There are also more mechanics, tradesmen, shopmen, &c., who now drift into the army. The husbandman and common labourer, from which class the majority of recruits were formerly drawn, no longer constitute the preponderating element. Then the labourer of to-day is better educated than his predecessors, and when in the ranks finds himself surrounded by a much superior set of companions than was the case a decade or two ago. In a word, the whole tone of the rank and file of the British army has improved. As a result the soldiers are more careful and better behaved; they are more sober and more clean. In building the new barracks at Aldershot especial care was taken to provide the soldiers with improved facilities for personal cleanliness. The men, being better educated and more intelligent, are also more careful. Many complex influences have been at work, more especially of late years, otherwise the evil effects of abolishing the Contagious Diseases Acts would have been even more marked than is actually the case. These evils still, however, constitute the gravest difficulty. What is to become of the abandoned wives of the soldiers who have gone abroad? How can women known to be diseased be prevented from frequenting the streets? In round numbers we may say that almost one out of every four soldiers quartered at Aldershot contracts venereal disease in the course of the year. Apart from the reduction in the efficacy of the army this implies, it also means that there is a great prevalence of venereal disease among the civil population, and this must in many instances culminate in abject pauperism. Thus the ratepayers are made to suffer. There are more paupers in Aldershot than anywhere in the neighbourhood. The number of in-door paupers in the Farnham Union in 1893 was equal to 17 per 1000 of the population; but in the Aldershot district it was equal to 22 per 1000. The widespread prevalence of immorality that must result from the gathering together of a large number of young unmarried men is always a grave matter. At Aldershot the difficulties are greater than usual, because the town is very small, has very few resources of its own, and it is burdened by the presence of a number of the abandoned wives of soldiers married without leave.

TUBERCULIN AND BOVINE TUBERCULOSIS IN THE STATE OF NEW YORK.

THE knowledge which has been acquired within recent years of the prevalence of bovine tuberculosis, more particularly in adult cattle and dairy stock, has excited considerable attention among public authorities in many countries. In Denmark and in Prussia, for example, the matter has been extensively taken up by the sanitary authorities of the State, and in our own country by the present Royal Commission on Tuberculosis; and, seeing the energy which the Health Departments of some of the States of the Union have thrown into all questions relating to the contagiousness of tubercle, it is no matter of surprise that the question of bovine tuberculosis has been widely attacked in America.

In an article in THE LANCET of Feb. 3rd, 1894, it was pointed out that a valuable method of diagnosing tuberculosis in cattle had arisen in Koch's tuberculin, and that with its aid efforts were being made in many directions to recognise tuberculosis

and to endeavour to exterminate it from herds such as pleuropneumonia can be exterminated. Such an effort has been made by the State Board of Health of New York, and the story of its action is to be found in vol. ii. of its annual report for 1894.

So early as 1892 a statute of the State of New York called upon its Board of Health—(1) to ascertain whether or not there exists in milch cows or other cattle in the State a cause of disease or danger to life, and (2) to devise means for averting the same and for preventing all injury from tuberculosis in milch cows. To this end ample powers were given to the Board to employ and fix compensation to medical and veterinary practitioners, to prescribe rules, to make and secure the enforcement of orders, and, finally, to destroy all cattle affected with tuberculosis, laying it down as the Board's duty, whenever tuberculosis is found to exist among milch cows or other animals, to suppress it promptly and to prevent its spread.

The Board proceeded with great promptitude to act upon this mandate. A staff of veterinary tuberculosis inspectors was appointed and rules drawn up for their guidance. These rules at the outset had relation to diagnosis chiefly on the strength of physical examination; but as the futility of this method soon became manifest the rules were modified so as to make tuberculin the cardinal test. Thenceforward, in the main, animals inspected were passed or slaughtered according to the results of tuberculin injections.

From the end of 1892 to the early months of 1894 the staff of inspectors appears to have caused the slaughter of over 1000 cattle, principally cows, on the ground of demonstrable or of suspected tuberculosis. What number were actually inspected and in what precise proportion tuberculin was used it is unfortunately impossible to gather from the report. If we add up the numbers given for different herds in the several counties we reach a total of over 20,000 inspected; but we find in the introduction to the report the reservation that "in many cases the same herd, or part of the same herd, is noted two or three times," and no data are given by which we can correct this error. It is apparent, however, that whether the 1000 slaughtered were among 20,000, or whether (as the introduction suggests) among a considerably smaller number, they indicate a very extensive and serious prevalence of the disease; for there can be little doubt, after reading the accounts of post-mortem examinations of the cattle condemned, that in a very considerable majority tuberculosis was present in one or another form. In some instances the reports of these examinations call for comment, and it is not always easy to agree with the diagnosis as given. Thus, on p. 247 the whole account of the post-mortem examination of Cow 5 (tabulated elsewhere as tuberculous) is an example of several equally dubious:—

"Lymphatics: Retro-pharyngeal enlarged; serous membranes, no calcareous deposits found; uterus, with foetus, full, six months. Diagnosis: tuberculosis."

We find, too, a number of cases in which confirmation of the inspector's diagnosis by a skilled pathologist would appear to be very desirable. Little if any examination for tubercle bacilli seems to have been made, and the special pathological reports that are given are somewhat meagre and inconclusive.

Among the undoubtedly tuberculous a point of considerable interest is the limited extent to which tuberculous lesions were frequently found. Taking at random the record of the slaughter of twenty-five animals in one herd (at pp. 233-245), we find that in twelve the tubercle was confined to calcareous glands (in one case only a few "pin-head deposits") in the thoracic cavity, without any affection of the lungs or organs elsewhere; while only in four or five of the remainder is any evidence given that the tubercle was becoming general or at all extensive.

The fact remains, however, that tuberculosis, whether slight or severe, was found in a very large number of the animals condemned, and we cannot but admire the energy with which the Board of Health has set itself to work to detect and destroy the disease. And in this connexion its methods of diagnosis, particularly the result of tuberculin injections, are worthy of careful study. Have the indications of tuberculin been sufficiently constant to give reasonable grounds for its administrative action? It is disappointing not to find an answer to this question in the report. Only casually, in the reports of a few inspectors, is any reference made to the source of the material (though it appears there are both a "U.S." and a "K" tuberculin), nor are we told whether

any method has been adopted to secure its uniformity, or, in the case of a number of the injections, what dose has been given. Again, while the Board, defining the normal temperature of cattle to be from 99° to 102° F., lays down that a "reaction" is a rise of 2° or more above the mean of two temperatures taken before injection, it has also directed its inspectors to use discretionary power in cases of doubt. The latter appear to have interpreted this permission in a liberal spirit, and to have condemned a number of animals which did not react according to the definition. But unfortunately they do not supply us with details in many of these cases, and in others the reason of slaughter is extremely difficult to understand. Perhaps the greatest difficulty of all is the absence of any system of control experiments. From the first the certainty of tuberculin seems to have been taken for granted. We may instance (from p. 114) the remark of an inspector, apparently perplexed at having slaughtered two cows innocent of tubercle post mortem, that in their case "the reaction was so positive that it seems scarcely probable that these animals were not tuberculous."

Some indications, however, may be obtained from those cases in which post-mortem examinations have been made upon animals whose temperatures before and after the injection have been fully recorded, and it is worth while to go through them and apply to each the definition of reaction given by the Board of Health. An analysis of 682 cases collected from the several counties may be put into the following table:—

	Number slaughtered.	Tuberculous.		Doubtful if tuberculous.		Not tuberculous.	
		No.	Per cent.	No.	Per cent.	No.	Per cent.
A. Undoubted reaction	569	534	94.0	16	2.7	19	3.3
B. Reaction doubtful, owing to temperature above 103° before injection ...	30	20	—	2	—	8	—
C. Reaction doubtful from other causes ...	28	18	—	1	—	9	—
Total of A, B, and C.	627	572	91.2	19	3.0	36	6.8
D. No reaction ...	55	16	29.0	12	22.0	27	49.0

* Including 25 cases where the post-mortem evidence of tuberculosis is extremely slight.

It will be seen at once in what a large proportion the indication of tuberculin has been found correct, but it will also be seen that it is by no means free from error. If we exclude the animals in B and C, whose reaction was doubtful, the error is only 3.3 or at most 6 per cent.; but to omit to recognise these doubtful reactions would be to pass 38 tuberculous animals out of 58. Adding them, therefore, we find the mistaken cases range between 6.8 and 9.8 per cent. On the other hand, tuberculous lesions were found in as many as 16 out of 55 animals that did not react, but were slaughtered notwithstanding by the inspectors for various reasons.

The existence of these errors appears to be a matter of considerable moment. If among the animals passed because they did not react there exists anything like the proportion of tuberculosis found post mortem in the non-reacting animals slaughtered, then the administrative action taken will have been of little use in the interests of the cattle. For them the theory acted upon is that tuberculosis in whatever form is infective, and if, therefore, in any herd a number of tuberculous animals escape detection so many centres of infection for the rest remain. And until we know more certainly what particular conditions of bovine tuberculosis are dangerous to man, we can hardly affirm that an incomplete destruction of tuberculous cattle, however extensive, is the simplest or most efficacious method for the protection of human health.

The reader of this report cannot but reflect that if, in spite of the want of exactness and uniformity of method that has been indicated, tuberculin has nevertheless been successful in diagnosing tubercle in so large a proportion of animals, what might not be expected of it if the conditions of its action were thoroughly investigated and properly defined? The New York Board of Health had a great opportunity; the country was alive to the danger, the Legislature gave the

Board a free hand in dealing with the question, and, judging merely from the report, it would seem that no condition was wanting to enable an accurate determination to be made of the conditions under which tuberculin is a trustworthy test. As it is, the Board has done much commendable work on a large scale, but appears to have made little endeavour to formulate at the outset any scientific basis for its action. After reading the report it is hardly surprising to discover that considerable dissatisfaction has arisen, and that the Legislature has been compelled to suspend the powers of the Board and appoint a commission to consider the question afresh.

UNQUALIFIED MEDICAL PRACTICE AND DEATH CERTIFICATES.

AN inquest was held at Coventry on March 15th before Mr. Charles Webb Iliffe, coroner for North Warwickshire, on the body of William Alfred Gumbley, the sixteen months old child of a bicycle polisher living at 4 court, 5 house, Leicester-street, Coventry. The case excited much interest in the city owing to the discussion which took place at the inquest as to the issue of the death certificate.

The mother of the child deposed that he had been healthy from birth, but on the previous Monday she noticed that he was very poorly. When her husband came home at dinner time she told him of the child's illness, and the father said to her, "Have you got a shilling?" and she replied "Yes." He then said, "You go and take the boy to Millerchip," and she took him to 4, Swanswell-place and saw "Dr." Millerchip.—The Coroner: Why did you call him "Dr. Millerchip"? Witness: That is what I have heard the Coventry people call him.—You did not know he was not a medical practitioner? If I had I should not have taken the child to him.—You only had a shilling? No, sir. I went to Millerchip's and when the door was opened I saw an assistant who took me into a room and "Dr." Millerchip came in with him.—Were there any other people there? No one else; only the "doctor" and his assistant. The latter looked at the child, said it was a very bad case, gave me a powder, and told me to take the child home and give him a warm bath.—Is it a fact or not a fact that you did not see the assistant at all? Both were there when I went the first time, but the assistant gave me the powder and "Dr." Millerchip went out. The assistant said the child was as bad as ever he could be.—What did "Dr." Millerchip say? He did not say anything whatever.—You were really consulting the other person, the assistant? Yes.—You paid a shilling to the assistant or to Millerchip? To Millerchip.—When you started from home whom did you think you were going to see, Mr. Millerchip or the assistant? I did not know whom I should see; I wanted to see anybody who could save my child. I went with the intention of seeing Mr. Millerchip.—Had you seen the assistant before? Yes. The witness went on to say that a few weeks before the child was taken to the Coventry and Warwickshire Hospital, but she was told that whooping-cough (from which he was suffering) was not treated there.—Whom did you go to with this child? "Dr." Millerchip.—You thought Mr. Millerchip was a doctor? Yes, I did.—Have you since learnt differently? Yes, or I should have my baby now.—Did you know that if your child died Mr. Millerchip had no power to give a certificate for burial? I did not know. I thought he was a doctor. On leaving Millerchip's house she took the child home and bathed him, but he got worse. She went to Millerchip again in the evening, and he then said to her, "I have done all that I can for the child." Her husband then said, "I will call in another doctor," and he went for Mr. Overton, surgeon, who came at 10.30 p.m.—Did Mr. Millerchip's assistant make any visit? No; I could not get "them" to come. The child died while her husband had gone to Mr. Overton's for medicine. She (the mother) went to Mr. Millerchip for a certificate, and he said he could not give one.—For what reason? Because we had called another doctor in.—Had you seen this assistant at Mr. Millerchip's before? No.—Did you only a little time ago see another assistant? Yes.—Mr. Overton declined to give a certificate. She and her husband went to Millerchip again the next morning, and he then gave a certificate, the cause of death being put as convulsions, secondly as exhaustion, and the paper was signed "Samuel Murphy, L.R.C.S.I."

Mr. Millerchip said, "We will give a certificate rather than have any bother about it."

The coroner, in reply to the foreman of the jury, stated that Mr. Millerchip was not entitled to give a certificate, he not being a qualified practitioner. Mr. Murphy was registered in Ireland. There had been (added the coroner) a number of cases that had been attended by Mr. Millerchip in people's own homes, and then an assistant had been called in at the last moment for the purpose of giving a certificate of death. The registrars had sometimes objected to accept these certificates without reference to the coroner. These assistants were, as it were, "covering" Mr. Millerchip and saving him from responsibility.

John Gumbley, the child's father, was next called, and he corroborated the wife as to the child being taken to Mr. Millerchip, whom he had heard spoken of as "a clever man."—The Coroner: Do you think he was clever as a doctor? Yes.—Did you know he was not legally qualified as a doctor at all? No. He knew a lot of people went to him, but had not heard of Mr. Millerchip visiting patients. The father went on to say that Mr. Overton, when he saw the child alive, thought that poison must have been taken. On his going to Swanswell-place for a certificate he told Mr. Millerchip he had called in another doctor, and Millerchip then said, "If you have called in another doctor it is nothing to do with me. I can give no certificate." He went a second time, and then Millerchip said to him, in the presence of the assistant, "You don't want your child to be cut open and hacked?" and he replied "No." Then Millerchip turned to the assistant and said, "You had better give him a certificate," and the assistant wrote one.

Thomas Golby, coroner's officer, deposed that the registrars of deaths in the city had called his attention to certificates of deaths of persons treated at 4, Swanswell-place. This was the fifth case since Jan. 1st where it was alleged that certificates were signed by assistants who had seen the patients only a short time before death. His investigations led him to believe that Mr. Millerchip had attended people not only at his surgery, but in their own homes.—The Coroner: As a professional man? Yes. Someone else has gone to the patient just before death, and then signed the certificate at death. He remembered a case of the sort that came before the coroner eighteen months ago. The assistant then was an old man, who admitted that he was called in for one visit before death.

Mr. Percy Edgar Overton proved that he and Mr. Edward Phillips made a post-mortem examination of the body of the child Gumbley, and that they were unable to say what was the cause of death. The child's organs were healthy. Mr. Phillips added that he was not in a position to say whether the secondary cause was exhaustion. All depended on what exhaustion meant.

The Coroner summed up the case for the jury, and commented on the impropriety of a medical man giving a certificate of death without full acquaintance with the case, and of a system of "cover" to an unqualified person.

The jury returned a verdict of "Death from natural causes."

ANÆSTHESIA IN THE LOWER ANIMALS.

NOT very long after the introduction of chloroform as an anæsthetic into medical practice, and when its beneficent and pain-suppressing powers had been fully demonstrated on mankind, inquiry began to be made as to why its merciful influence should not be extended to the domestic animals when they had to undergo painful operations, especially those of a protracted kind; and we remember reading a most eloquent appeal for its employment in the case of the horse in a clever little book, published nearly forty years ago, by Sir Francis B. Head, entitled "The Horse and his Rider." This appeal is perhaps as necessary now as it was when first made, and certainly it should be brought again to the notice of those who, for some reason or other, do not resort to anæsthesia, general or local, when plying the cutting instrument, the burning iron, or other pain-producing agent on animals. In the section of his book on chloroforming horses, after dwelling on the unspeakable boon that had been conferred on man by the application of anæsthetics in the abolition of suffering and agony, he says: "Now, if in

return for this extraordinary alleviation, or rather annihilation, of all sufferings under surgical treatment, man should deem it his duty to render thanks to that Omnipotent Power from which it has proceeded, is it possible for him practically to perform any more acceptable act of acknowledgment than to allow the dumb creatures in his service to participate in a blessing which, by Divine authority, has been imparted to the possessors, not exclusively of human reason, but without favour or exception of animal life? As regards his horses, the performance of this duty is especially incumbent; for not only, like all other animals, are they liable to the accidents and ills that flesh is heir to, but some of the cruellest operations to which they are subjected—such, for instance, as cutting off and cauterising their tails, burning their sinews with red-hot irons, dividing and cutting out a portion of a nerve (sensory), with other excruciating operations on young horses, under which they are often heard to squeal from pain—are inflicted on them to comply with either a useless as well as a barbarous fashion; or to enable them 'to go for another season's hunting'; or for the attainment of conveniences of which the horse derives not the smallest share; or to make them 'sound enough to sell'; and as the high-bred, broken-down hunter has no voice to ask for mercy, as he cannot boast of possessing reason, or as he has inherited no knowledge, as he has no power to bequeath any, as his whole energies have been devoted to the service and enjoyments of man, by whose mechanical contrivances he is now 'cast' with his four feet shackled together, lying prostrate on a heap of straw, just before the red-hot iron sears his overstrained sinews or the sharp knife is inserted into his living flesh—surely in a civilised country like England some high power should be authorised to exclaim, not 'Woodman, spare that tree!' but '*Sportsman, save that horse!*' by chloroform from the agonising torture to which you have sentenced him. You are a man of *pleasure*—save him from unnecessary *pain*. You are a man of *business*—inscribe in that ledger in which every one of the acts of your life is recorded, on one side how much *he* will gain, and on the other, *per contra*, how very little you will lose, by the evaporation of a fluid that will not cost you the price of the shoes of the poor animal whose marketable value you have determined, by excruciating agony to him, to increase."

This urgent appeal concludes with another allusion to the benefits chloroform has conferred on the human species, and adds: "If, therefore, man to this enormous extent is benefited by chloroform, what right has he to withhold it from his own animals, to whom, not only in equity, but by the laws of God it belongs as much as it belongs to him? Their claims are so affecting and so obvious, the remedy that would save them from all pain is so cheap and simple, that we feel it is only necessary to appeal to the public to obtain by acclamation a verdict in their favour."

Notwithstanding this and similar appeals and remonstrances, the employment of anæsthetics has made slow progress in veterinary practice, expense, trouble, and time being usually the pleas offered for their non-adoption. A number of veterinary surgeons, however, resort to them on every possible occasion, and, putting the avoidance of pain on one side, testify to the advantages they derive from them; indeed, there are some operations which could not be attempted with any hope of a successful result unless the animal is under the influence of an anæsthetic. Even in cases of difficult parturition, partial anæsthesia, especially in the mare, is found to be most advantageous in effecting delivery. Of all animals the horse is the one to which chloroform can be most safely administered; in fact, it is sometimes an arduous task to destroy this creature by inhalation of the drug. It has been given to hundreds—it might be said thousands—of horses, almost undiluted with air, and with absolute impunity. But some veterinary surgeons imagine that there may be danger in this rapid anæsthesia, and advise the mixture of chloroform and air, which, if it requires a longer time to produce the necessary degree of narcosis, is safer. However this may be, it is gratifying to find that attention is being increasingly directed to this matter; and among those who have distinguished themselves in this direction, and have laboured to dispel the prejudice which still opposes the use of chloroform, must be named Mr. Wallis Hoare, F.R.C.V.S., Cork, who, in advising the dilution of chloroform vapour with air during inhalation, has improved on the ordinary apparatus by a modified bag and foot bellows, which appears to be easily worked and effective. For adult

horses the quantity of chloroform required in this apparatus is from one and a half to two ounces, the time occupied in producing complete anæsthesia varying from ten to fifteen minutes, and Mr. Hoare regards loss of muscular power in the limbs and loss of sensation on striking the animal firmly on the quarter as the best indications of the proper stage at which operations may be commenced. Mr. Hoare is evidently an enthusiast in this humane practice of veterinary surgery, and it is earnestly to be hoped that his example may be largely followed; for though all animals should receive merciful consideration when they have to undergo operations, surely none of them is more entitled to this than the horse, whose muteness under the infliction of pain seems to lead people to think that he suffers but little—a grave error, but one which has caused him to be more abused and tortured than all the others put together.

THE

COMPLIMENTARY DINNER TO SIR JOHN E. ERICHSEN, SIR J. RUSSELL REYNOLDS, AND SIR JOHN WILLIAMS.

SIR JOHN E. ERICHSEN, Sir J. Russell Reynolds, and Sir John Williams were entertained at dinner on Wednesday evening by their colleagues, friends, and pupils at the Criterion Restaurant. The Vice-President of University College, Lord Reay, presided.

Lord REAY, in rising to propose the health of the three distinguished guests, said it was impossible to leave out of sight the extraordinary revolution which the science of which they were the illustrious representatives had undergone. After briefly tracing the development of their professional knowledge and touching upon the recent discoveries of Roux with reference to diphtheria; of Lord Rayleigh and Professor Ramsay with regard to argon and helium; of Kitasato with regard to the microbe of the plague; of Sir Joseph Lister, Pasteur, and others, he said the conquests which had been achieved were tangible ones, tending to make life more worth living. Referring to the efforts which had been made to rid the profession of quackery, he would like to see other professions adopt something similar to the Medical Register. He saw little signs, however, of getting rid of quacks in other professions, and in this respect the medical profession in England had been singularly fortunate. To belong to such a profession was in itself a great honour. To rise to a leading position in the profession such as that which their three guests held made it superfluous to enter into biographical details. Of Sir John Erichsen it was sufficient to mention that he was the author of a standard work on the Science and Art of Surgery; and those who had worked with him, for him, and under him, in University College knew the stimulating power of his work. His example had left an indelible mark. Sir Russell Reynolds' "System of Medicine" alone entitled him to the position he held, and Sir John Williams had mastered in all their medical and surgical ramifications the science and art of gynaecology. In offering congratulations to these gentlemen it could not be forgotten that this official recognition of their talents followed the natural selection of the fittest by those best able to judge. It was a noteworthy fact that in the medical profession the State was conspicuous by its absence, except when it created baronets. The medical schools were self-governing institutions, the hospitals were not aided or controlled by County Councils, and the Royal Colleges of Physicians and Surgeons were corporations which were absolutely their own masters. It was a situation which was absolutely unique in the world, and if it could be followed by other professions would be to their advantage. It was a great honour to University College that its medical school claimed all three of their guests, and that in Sir John Erichsen they had a past President of the Royal College of Surgeons, and in Sir Russell Reynolds the actual President of the Royal College of Physicians. Their position had been attained not only by the splendour of their intellect, but by the self-sacrifice of which throughout their careers they had given such abundant proof. Lord Reay then paid a tribute to the memory of the late Sir William Savory, testifying to the good work he had done on the Royal Commission on the University of London.

The toast of the evening was spoken to by Sir Henry

Thompson, who gave some interesting reminiscences, and by Dr. Champneys, who spoke of his associations with Sir John Williams.

Sir JOHN E. ERICHSEN, in responding, expressed the gratification he felt for the reception which had been accorded to him that evening. The distinction which had been conferred upon him by Her Majesty was most gratifying, but there was the proverbial drop of bitter in the cup. "It comes too late." In looking down that long vista of his life which extended from the commencement of his work to the present day, he could truly say that he had ever tried to so shape his work that it might conduce to maintain the honour and dignity of the profession to which he belonged, both in public and in private. If there was one matter more gratifying to him than another it was that the distinction conferred upon him was not a personal one but was conferred through an individual upon the profession. The public at large knew little of the inner life of the profession, of the great intellectual activity of its members, of its splendid achievements in scientific work, of its devotion to duty, and of its self-sacrifice in the cause of charity. These characteristics were common to the humblest as well as the most exalted members of the profession, from the dresser who imperils his life in attending to a patient to the work of Presidents of the Royal Colleges. The debt of gratitude which he owed to University College he could never repay, the opportunities in early life for achieving whatever success he had attained and the formation of many friendships. To be president of University College was one of the highest honours which could befall a professional man, especially when he was the successor of such men as Lord Brougham, Mr. Grote, Lord Belper, and Lord Kimberley.

Sir J. RUSSELL REYNOLDS said that nothing could be more gratifying to any member of the medical profession than that evening had proved to him. He stood between his old master, Sir John Erichsen, who was subsequently his colleague and always his friend, and Sir John Williams, an old pupil, then his colleague and afterwards his friend. Something had lately been said about University College being a favoured one, but it had always enjoyed a large share of University honours, and had been productive of men of distinction not only in the medical but also in the legal professions. In the former he mentioned Sir Joseph Lister and Sir Richard Quain, and in the latter Sir G. Jessel and the present Lord Chancellor. Sir Russell Reynolds then concluded a brilliant little speech by relating a personal anecdote. He was called to see a gentleman, and the next day a friend of his called upon the patient. On the friend inquiring of the butler how the gentleman was, he replied, "Oh, he is much better and quite happy now. He has just seen Sir Joshua Reynolds, the president of the Royal Academy."

Sir JOHN WILLIAMS also responded.

Sir WILLIAM BROADBENT proposed the health of the Chairman, remarking that he did not think any honours bestowed within his recollection had been received with such unanimous goodwill and support on behalf of the profession as those which had been conferred upon their guests.

During the evening Dr. F. Roberts admirably rendered the charming ballad "The Anchor's Weighed."

THE WOMEN'S FREE HOSPITAL, SOUTHAMPTON.

We have received the following statement from the Hon. Secretaries of the Southampton Medical Society with a request, as will be seen, for its publication:—

"Certain facts relating to the constitution, management, and work of the above hospital having come to the knowledge of several members of the Southampton Medical Society in the course of their individual practices, and also to the members generally in the ordinary course of the work of the society, which are deemed by them to be of serious public importance, we are instructed by the society to request the Editors of THE LANCET, in the public interest, to publish the following statement of facts:—

"In November, 1889, a few persons met and discussed the subject of starting in Southampton a free hospital for the treatment of the special diseases of women, and a committee of five was appointed and the hospital started at 1, Bellevue-

terrace. In June, 1890, it was removed to 17, Ordnance-road, and in June, 1891, to 2, Middle Portland-terrace, and since then the out-patients' department has been removed to a new building in Portland-terrace, where it is now carried on. Professor Lawson Tait was stated to be the consulting surgeon and Mr. Eliot the medical officer. Subsequently the committee announced that Dr. Playfair had consented to act as consulting physician, and had promised his support. The committee, with the hospital thus formed and staffed, in about December, 1891, issued an urgent appeal to the public for support, and in each of the three reports subsequently issued by them a similar appeal is made. This appeal has in some small degree been responded to by public subscriptions and donations.

"Notwithstanding that the hospital is called 'free,' it appears from the reports issued by the committee that patients require letters of recommendation, to be renewed every two months, subscribers of one guinea annually receiving seven letters, those subscribing 10s. 6d. three letters, and those subscribing 5s. one letter. In-patients have to pay the medical officer a sum of two guineas a week and are treated at his private surgical home, which in an extract from a newspaper notice incorporated in an advertisement of the home contained in a local directory is described as a place where 'patience and kindness combined with vast experience and skill can hardly fail to bring about a speedy recovery.' That the committee are responsible for the in-patients as well as the out-patients is shown by the fact that in their published statement of the patients treated they include in-patients. In their first report they state that 'a ward has been efficiently fitted up with all modern appliances for the reception of in-patients'; and they add, 'As soon as funds will permit all such cases will be offered the boon of being admitted for treatment as in-patients at the hospital.' In their second report they state that an arrangement had been made with their medical officer to receive hospital patients at a charge of two guineas a week, payable by the patient, at a house he had taken for his private patients; and the medical officer, in his report to the committee—which was adopted by them and published with their report—stated, 'I am glad to state we can now treat in-patients and out-patients under a different roof.' In his report the medical officer thought right to inform the committee that he had a good staff of nurses thoroughly trained in the special branch of work they were engaged in. This seems to imply a most incredible ignorance on the part of the committee as to matters they should have under their control. In their third report the committee state that 'patients requiring operations have been admitted into beds set apart for hospital patients at 8, Carlton-crescent, according to the arrangement that the committee made with their medical officer last year.' The medical officer, in his report, adopted and published by the committee, states, 'I have admitted cases for operations into 8, Carlton-crescent,' and adds that 'twenty-four abdominal sections have been performed, in addition to other operations.' In a letter from the hon. secretary to the hospital in answer to an inquiry for information, under date July 16th, 1894, he states: 'The in-patients have been treated at Rockstone House' (or 8, Carlton-crescent) 'in the free ward,' and adds the somewhat extraordinary statement, 'I am not in a position to answer your question, not having access to the books.'

"The reports of the committee contain no statement of the number of patients treated, distinguishing in-patients from out-patients, or any detailed particulars of the operations performed, or the deaths after operation, as is usually given in reports of a like kind. The published accounts are also very meagre, giving no particulars of the sums paid by patients or the cost of in-patients. In their second report the committee state that their medical officer asked for permission to furnish rooms at 2, Middle Portland-terrace (the house used as the hospital) for his private patients, and such permission was given; but although the charity bore the rent and other expenses of the house, no reference is made in the accounts of any sum received from the medical officer for the accommodation thus afforded him.

"Seeing that (1) the committee were taking on themselves the responsibility of very serious operations involving risk of life, and which, if not absolutely necessary, were merely useless mutilations; (2) there was only one medical officer residing in Southampton, the consulting surgeon residing in Birmingham and the consulting physician in London; (3) the hospital is styled 'free,' while letters of recommendation are required and in-patients are expected to pay two guineas

a week; (4) the committee seem not to have any proper control over the in-patients' department; and (5) the absence of rules to govern the hospital, the Medical Society, as representing the profession, felt that a grave responsibility rested on them, and the matter having been formally brought to their notice on Nov. 6th, 1894, in a paper on the subject read before them by Mr. Bullar, it was resolved 'that a copy of Mr. Bullar's paper be sent to each member of the committee of the Women's Free Hospital, and also that information be asked for on the following points: (a) the number of in-patients that have been treated, (b) the diseases from which they suffered, (c) the number and nature of the operations performed, (d) the result of the operations, and (e) the mortality after operations and general mortality.'

"To this communication the committee of the Women's Free Hospital replied in a letter from their hon. secretary under date of Dec. 5th, 1894, who, while repudiating any obligation to give the Medical Society any information whatever, regretted the insufficiency of their reports in past years, and the committee stated that 24 abdominal sections had been performed in the year 1893, involving 4 deaths, and of these Mr. Tait saw 19 and assisted at 12 of them; but nowhere is there any statement showing that the universal rule in the profession, in hospital practice, not to perform a serious operation involving risk to life, except under urgent necessity, without previous consultation, was followed. Appended to the reply is a statement from the case and operation books of the hospital, giving particulars of the operations performed. From this statement and the reports it appears that in the year 1893, of 215 patients treated at the hospital, 24, or 1 in every 9, were submitted to abdominal section, whereas from the published reports of other similar special hospitals the ratio appears to be about 1 in 40.

"The reply of the committee was considered by the society at a meeting on Dec. 20th last, at which twenty-eight members were present, and with one dissentient the following resolutions were passed:—(1) 'That in view of the frequency with which abdominal sections have been performed and advised at the Women's Free Hospital, and of the fact that operations have been performed without previous consultation of a satisfactory kind, the Medical Society feels that it is a matter of grave doubt how far the operations have been justified. The society is also of opinion that the management of the hospital is lax, and that the financial arrangements are most peculiar in a hospital called "Free." The Medical Society therefore feels bound in the public interest to demand that an inquiry into the whole work and management of the hospital be held by an independent and competent committee, as has recently been done in the case of the Chelsea Hospital for Women. The society suggests this as a means whereby further publicity may be avoided. The Medical Society is of opinion that if the work of the hospital has been good an inquiry cannot fail to benefit it, and that if it has been bad the committee of the hospital cannot wish that it should continue. The Medical Society suggests that a committee of three be appointed to hold the inquiry, and that one member be nominated by the Women's Free Hospital and one by the Medical Society, the third being nominated by the other two.' These resolutions were sent to each member of the committee and medical staff of the hospital, together with a letter, on Jan. 7th last.

"Dr. Playfair, in a letter addressed to the committee of the hospital, has stated in reference to the inquiry asked for, 'In my opinion it is one which should be at once carried out. When the work and management of a charitable institution such as yours has been publicly impugned full inquiry should be courted. Nothing could be better for such an institution than a favourable report from a qualified and unbiased committee of investigation. If this proposal is declined, the public will naturally come to the conclusion that there is something it is wished to conceal.' To these resolutions the hon. secretary of the Women's Free Hospital replied on Feb. 2nd last, stating that the committee 'declined to admit the right of the society to interfere in matters relating to the constitution and government of the hospital,' and that 'the Medical Society have no right whatever to demand an investigation of the affairs of the hospital.' He further added that 'the issues involved are far too serious to warrant my committee in agreeing to such a proposal as your society has made, it would not afford them that complete satisfaction which they are anxious to obtain,' and proceeded to state that it was the duty of the society to acquaint the committee with the particulars of the evidence in their possession in support of the charges, and that upon this

being done the committee would have a full, impartial, and thorough investigation. He also stated that the committee wished to receive full particulars of the charges, so that they, as the responsible governing body of the hospital, might have an opportunity of investigating them. In the same communication the committee, speaking of their medical officer, state, 'it is perfectly well known that Mr. Eliot is specially skilled in cases of this kind' (i.e., diseases peculiar to women) 'and that his skill as a surgeon is too well known to need any confirmation at their hands.' The society have, however, been unable to ascertain that he has ever made any exceptional study of the subjects of which his committee thus attribute to him a special knowledge, or that he has done anything to differentiate himself from the rank and file of general practitioners in this particular matter.

"The society, feeling that the committee, being the persons responsible for the mismanagement of the hospital (if any), could not bring unbiased and impartial minds to bear on the subject of the charges, instructed us to write on Feb. 7th last declining to furnish the committee with the evidence in the possession of the society, more especially as the committee had already declared that they were 'loth to believe without absolute proof that women could have operations performed on them unnecessarily.' However, in deference to the wishes of the committee, we again repeated the charges in these words: '1. That, having regard to the appalling frequency with which abdominal sections have been performed in the Women's Free Hospital (one in every nine of all patients treated), in some instances without previous consultations of a satisfactory kind, and to the many instances known to our committee in which similar operations were advised, though not performed, and now demonstrated to be unnecessary—which if included would seriously increase the ratio—a grave suspicion arises that some at least of the operations performed cannot be justified. 2. That the management of the hospital is lax. 3. That the financial arrangements are most peculiar in a hospital called "free."

"We again asked if the demand of the society for an inquiry would be complied with, and promised that the society would lay the evidence in their possession before any unbiased tribunal and give every assistance in their power to arrive at the truth. On Feb. 13th last the hon. secretary of the hospital wrote to the society, stating that 'the society having failed to bring any specific charge against the hospital or its medical officers, as requested in the letter referred to' (namely, his letter of Feb. 2nd), 'my committee decline to continue the correspondence until this is done.' In consequence of the committee declining the inquiry proposed, Dr. Playfair has resigned his position as consulting physician to the hospital.

"The inquiry asked for having been refused, the Medical Society feel it their duty, in the public interest, to ask the Editors of THE LANCET to publish this statement of what has occurred, in order to relieve themselves of the responsibility in which silence on a matter of which they have peculiar opportunities of being better informed than the general public would involve them.

"R. D. H. GWILLIM,

"NORMAN ALDRIDGE,

"March 9th, 1895. Hon. Secs., Southampton Medical Society."

We publish the statement of the hon. secretaries of the Southampton Medical Society, agreeing with them that *prima facie* the matter is one that demands publicity. We have before us a copy of the annual report of the Women's Free Hospital for Treatment of Special Diseases for 1894. This document, it appears to us, contains certain of the particulars whose absence the secretaries of the Southampton Medical Society reprobate. On the other hand, it does not constitute in itself an answer to charges of mismanagement, and that is what the communication from the secretaries of the Southampton Medical Society amounts to.

WORCESTER DISPENSARY PROVIDENT MEDICAL INSTITUTION.—The annual meeting of the supporters of the Worcester Provident Dispensary was held on March 26th, the Rev. W. R. Longhurst being in the chair. The report showed that the total number of names on the books was 9053, being an increase of 100 upon last year's figures. The financial state of the institution was shown in the report to be satisfactory.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On certain localised Outbreaks of Diphtheria at Crofton and Orpington by Dr. S. Monckton Copeman.—The report in question discusses a number of comparatively small and yet very fatal occurrences of diphtheria in the Bromley rural sanitary district, and much of their interest lies in the obscurity attaching to the causation of the disease, and this although all the circumstances of the majority of the cases seemed more than usually accessible. Typical amongst the attacks was one at an old mansion known as Crofton Court, where between February and May five cases occurred with three deaths. There were certain chances of the importation of a definite infection, although none could be absolutely proved. But, admitting such importation, the infection seems to have clung with tenacity to the premises, notwithstanding the adoption of measures of prevention. From this point of view Crofton Court is a place of interest, and it exhibited conditions which can hardly be said to be rare in old country houses to which diphtheria has clung in somewhat the same fashion. The house itself had certain definite sanitary defects, but many of these were remedied on the occurrence of the first case. The site was, however, very damp, water was near the surface, and a cellar exhibited conditions showing that damp air had constant access to the interior of the house. Dampness was also favoured by thick trees, which overshadowed some of the windows and thus excluded sunlight. Then, again, there had prevailed in connexion with these defects a predisposition to sore-throat of an undefined sort amongst the members of the household. And, lastly, there was the difficult question of the possible influence of the offensive carting about of "London manure" in close proximity to the house. Some will find in one or more of these conditions ample to explain the cause itself of diphtheria; others will regard them mainly as favouring the reception of an external infection due to importation and the retention of that infection when once introduced. The various points are discussed at some length by Dr. Copeman, and we could have wished that this report had found a place amongst those which are placed on sale. Incidentally Dr. Copeman found it necessary to deal with the so-called "Bexley system," which has been devised with a view of getting rid of, or at least postponing, the question of drainage and sewerage. He distinctly condemns it. Any system under which cesspools are to be emptied by pumping machinery and tank carts can only be regarded as possessing the elements of efficiency provided the cesspools are really watertight. In the case under discussion they are leaky cesspools, and in a waterlogged soil; they fail to secure the proper disposal of all the liquid refuse, and they perpetuate the waterlogged state of the soil instead of aiming at lowering the high level of subsoil water, which is a distinct drawback to the healthiness of the area here under consideration. Under these circumstances Dr. Copeman advised the Bromley rural authority no longer to delay the construction, in connexion with the Orpington sewer, of a sewerage system to serve the Crofton district.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Pudsey Urban Sanitary District.—Dr. W. Lovell Hunter, in the introduction to his annual report for 1894, gives some excellent advice to the new district council as to their duties and responsibilities under the Public Health Acts, and we trust that this year's report will show that the advice has not been thrown away. The new council have been given a good start, inasmuch as the general death-rate for 1894, which was 14.6 per 1000, was the lowest yet recorded. Dr. Hunter reminds the council that the low death-rate cannot be entirely attributed to local causes, but he considers that there are three sanitary measures which have in particular had their effect—i.e., improved scavenging, prevention of lead poisoning, and a better provision for checking the spread of infectious disease. In the matter of compulsory notification Dr. Hunter, in urging his sanitary authority to adopt the Act, points out that Leeds, the only large town in the West Riding of Yorkshire not previously under the Act, embraced its provisions last year, and that 83 per cent. of the total

West Riding population are now under notification. Perhaps the new Pudsey council will see their way shortly to adding their population of 13,900 to the total. Dr. Hunter did not hear of a single case of lead poisoning during 1894, although it appears that the water supplied to the district still retains the power of acting upon lead, as evidenced by analyses of samples drawn in the early morning from a lead pipe 185 feet long. The monthly averages of lead ranged from 0.06 to 0.19 gr. per gallon, the lowest average being in August and the highest in April. The analyses show a very decided improvement on those for 1892, though not in all cases as compared with those for 1893; indeed, in some months the analyses for 1894 show an increase on those for the preceding year. There are in Pudsey few mill chimneys in proportion to its area, but Dr. Hunter reports that frequent complaints as to the smoke nuisance reach him; he points out that a reasonable smoke limit adopted by the council and enforced would soon improve the condition of the town.

West Hartlepool Urban Sanitary District.—Dr. Samuel Gourley reports that during 1894 the general death-rate of his district was 14.6 per 1000 of the population, and the infantile mortality 125 per 1000 registered births. There were in the period under review eleven cases with five deaths from small-pox; not one of the fatal cases showed signs of being vaccinated. Dr. Gourley condemned during the year seventeen carcasses on account of extensive tuberculosis, and he considers that in cases such as these, where the butcher has bought the beast in open market, compensation should be allowed. The smoke nuisance could, Dr. Gourley reports, be much reduced by careful stoking, and he thinks that unless proceedings are taken in some of the worst cases there is but little chance of improvement taking place. It is not clear why the sanitary authority are averse to relieving the population of West Hartlepool from this excess of smoke.

Short Heath Urban Sanitary District.—In this district, which contains a population of but 2667, there seems to be considerable difficulty in the matter of isolation accommodation, and Mr. John Hartill, the medical officer of health, proposes that the district shall for the purpose of small-pox hospital accommodation be grouped with others under the Isolation Hospital Act, 1893, while for other infectious disease he advises that six beds be provided in Short Heath. There were 90 cases of small-pox in Short Heath during 1894, the death-rate among the unvaccinated being more than four times greater than among the vaccinated.

Poole Urban and Port Sanitary Districts.—Dr. Herbert Lawton, through his annual report for 1894, impresses upon the inhabitants of his district the fact that it is incumbent upon the householder or nearest relative to notify cases of infectious disease to him, and that their responsibilities in that direction are in no way relieved by the medical certificate. During 1894 it appears that 36 out of 105 cases were not notified by the householder. We are glad to see that Dr. Lawton draws attention to this point. The methods of excrement disposal in Poole proper were, to judge by a report from one of the medical inspectors of the Local Government Board, anything but satisfactory; indeed, the accounts given of the proximity of privy cesspits to dwellings and the soaking of liquid filth up the walls were such as to render changes imperative. We are glad, therefore, to be able to record that the sewage disposal scheme has been begun, and also that during 1894 twenty old privy vaults were filled in. The sanitary condition of the bakehouses and slaughterhouses in Poole is apparently not as it should be, but there is no reference in Dr. Lawton's report as to dairies, cowsheds, and milkshops; no doubt, however, having regard to the importance of this matter both to Bournemouth and Poole, they are well looked after. No case of infectious disease has, Dr. Lawton reports, been notified from any of the vessels frequenting the port, and the health of the seamen has, he states, been satisfactory. In referring to the machinery for cholera prevention, we note that Dr. Lawton speaks of a "quarantine" station. It would, perhaps, be as well in speaking of cholera to avoid this word and to use the terms of the Cholera Order.

Chelmsford Rural Sanitary District.—The defunct Chelmsford rural sanitary authority now replaced by the rural district council may, as Dr. Thresh observes, look back upon their work with satisfaction; and we will add that if the new council carry on the work of progress initiated by their predecessors their district will soon be one of the best-equipped rural areas in the county. Dr. Thresh's reports are always cheerful reading because those portions

of them having reference to sanitary improvements bear signs of steady progress. For instance, in the report now before us, that for 1894, we read under the head of improvements effected during the year of a new water-supply for Woodham Ferris, Retterdon, East Hanningford, and Ranwell; of the provision of an isolation hospital after the plans of the Local Government Board, in which, by the way, the families of labourers will be admitted free of charge; and of the adoption of new and important by-laws. Under the head of improvements contemplated we read of schemes already far advanced for fresh water-supplies and the provision of a disinfecting apparatus. It seems, too, that the sanitary authority has recently obtained by-laws applicable to all the more populous parishes with respect to the offensive trades enumerated in the Public Health Act. We notice with regret that the Essex County Council is not very energetic in public health matters. For instance, in referring to some houses which are a danger to the public in consequence of their dilapidated condition, Dr. Thresh observes: "Our clerk having ruled that it is the duty of the county council to deal with such dangerous structures, nothing will probably be done until someone is injured"; and, again, in discussing the effluent of sewage farms: "If the county council paid any attention to the condition of our rivers, doubtless they would insist upon a higher standard being reached." In dealing with the prevalence of infectious disease Dr. Thresh refers to the manner in which the practice of medical men differs in regard to cases of an infectious character; in some cases he (Dr. Thresh) finds every precaution taken, in others but few. More especially is the absence of precautions discoverable in slight cases of diphtheria. Dr. Thresh observes as to this that if a case is sufficiently suspicious to warrant notification it is sufficiently serious to necessitate the most complete isolation possible under the circumstances.

Wimbledon Urban Sanitary District.—The general death-rate for this district for 1894 was, Mr. Evelyn Pocklington tells us, the lowest during the last eighteen years—i.e., 10.3 per 1000. In a case where the mother of two children suffering from scarlet fever neglected to duly notify the medical officer of health the bench inflicted a fine of 10s. for each case. Mr. Pocklington reports that considerable discontent has been evinced during the year owing to the unsatisfactory state of the fever hospital, and he insists upon the importance of erecting a more suitable building. New by-laws in regard to pig-sticking have recently been adopted, and their enforcement has resulted in considerable benefit. Mr. Pocklington thinks, however, that in certain parts of his district the prohibitive distance of pigsties from dwellings should be 150 ft. instead of, as at present, 100 ft.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6693 births and 5635 deaths were registered during the week ending March 23rd. The annual rate of mortality in these towns, which had been 35.0 and 32.2 per 1000 in the two preceding weeks, further declined last week to 27.7. In London the rate was equal to 26.0 per 1000, while it averaged 29.0 in the thirty-two provincial towns. The lowest rates in these towns were 18.9 in Birkenhead, 19.9 in Swansea, 20.6 in Halifax, and 20.7 in West Ham and in Nottingham; the highest rates were 36.4 in Blackburn, 36.5 in Manchester, 37.1 in Wolverhampton, 38.1 in Oldham, and 47.5 in Brighton. The 5635 deaths included 314 which were referred to the principal zymotic diseases, against 338 and 302 in the two preceding weeks; of these, 100 resulted from whooping-cough, 72 from measles, 50 from diphtheria, 39 from diarrhoea, 29 from scarlet fever, 22 from "fever" (principally enteric), and 2 from small-pox. No death from any of these diseases was recorded last week in Huddersfield or in Halifax; in the other towns they caused the lowest death-rates in Bristol and Portsmouth; and the highest rates in Wolverhampton, Bolton, Manchester, Blackburn, and Newcastle-upon-Tyne. The greatest mortality from measles occurred in Brighton, Plymouth, Bolton, Manchester, and Sheffield; from scarlet fever in Wolverhampton; and from whooping-cough in Norwich, Leicester, Blackburn, and Newcastle-upon-Tyne. The mortality from "fever" showed no marked excess in any of the large towns. The 50 deaths from diphtheria included 24 in London, 5 in Leeds, 4 in Birmingham, 3 in Manchester, and 3 in West Ham. One fatal

case of small-pox was registered in Derby and one in Liverpool, but not one in London or in any other of the thirty-three large towns. There were 58 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, March 23rd, against 68, 56, and 57 at the end of the three preceding weeks; 14 new cases were admitted during the week, against 8 and 12 in the two preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1587, against 1621, 1619, and 1615 on the three preceding Saturdays; 184 new cases were admitted during the week, against 143, 141, and 133 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 1448, 1366, and 1031 in the three preceding weeks, further declined to 740 last week, but were 254 above the corrected average. The causes of 74, or 1.3 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Bradford, Leeds, Sanderland, and in eleven other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Leicester, Hull, and Newcastle-upon-Tyne.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined in the three preceding weeks from 42.8 to 35.1 per 1000, further fell to 31.2 during the week ending March 23rd, but exceeded by 3.5 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 25.1 in Greenock and 27.2 in Aberdeen, to 40.9 in Edinburgh and 42.0 in Leith. The 900 deaths in these towns included 56 which were referred to measles, 27 to whooping-cough, 17 to diarrhoea, 9 to diphtheria, 5 to scarlet fever, 1 to "fever," and not one to small-pox. In all, 115 deaths resulted from these principal zymotic diseases, against 144 and 110 in the two preceding weeks. These 115 deaths were equal to an annual rate of 4.0 per 1000, which was 2.5 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 72 and 48 in the two preceding weeks, rose again to 56 last week, of which 19 occurred in Edinburgh, 17 in Leith, 9 in Glasgow, and 9 in Aberdeen. The deaths referred to whooping-cough, which had been 39 and 22 in the two preceding weeks, increased to 27 last week, and included 17 in Glasgow, 3 in Aberdeen, and 3 in Leith. The 9 fatal cases of diphtheria exceeded those recorded in any recent week, and included 6 in Glasgow. The deaths from scarlet fever, which had been 6 and 10 in the two preceding weeks, declined again to 5 last week, of which 3 occurred in Glasgow and 2 in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had declined from 544 to 385 in the three preceding weeks, further fell to 313 last week, but were nearly three times the number recorded in the corresponding week of last year. The causes of 48, or more than 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 48.8 and 42.4 per 1000 in the two preceding weeks, rose again to 45.0 during the week ending March 23rd. During the past twelve weeks of the current quarter the death-rate in the city has averaged 36.1 per 1000, against 26.4 in London and 31.1 in Edinburgh. The 302 deaths registered in Dublin during the week under notice showed an increase of 18 upon the number in the previous week, and included 7 which were referred to the principal zymotic diseases, against 14 and 9 in the two preceding weeks; of these, 5 resulted from small-pox and 2 from "fever," but not one either from measles, scarlet fever, diphtheria, whooping-cough, or diarrhoea. These 7 deaths were equal to an annual rate of 1.0 per 1000, the zymotic death-rate during the same period being 1.4 in London and 5.3 in Edinburgh. The fatal cases of small-pox, which had been 4, 5, and 4 in the three preceding weeks, were 5 last week. Since the commencement of the current year no fewer than 77 deaths from small-pox have been recorded in Dublin. The 302 deaths registered in Dublin last week included 39 of infants under one year of age and 102 of persons aged upwards of sixty years; the deaths both of infants and of elderly

persons exceeded those recorded in the preceding week. Four inquest cases and 4 deaths from violence were registered; and 74, or nearly a fourth, of the deaths occurred in public institutions. The causes of 20, or nearly 7 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

SURGEON-COLONEL W. S. M. PRICE, A.M.S., will succeed Surgeon-Colonel A. F. Churchill, M.D., as Principal Medical Officer at Woolwich next month.

INDIA AND THE INDIAN MEDICAL SERVICES.

The following appointments are notified:—Surgeon-Lieutenant-Colonel A. Scott Reid (Bengal), Medical Officer, 2nd Battalion, 4th Gurkha (Rifle) Regiment, to officiate as Civil Surgeon at Quetta until further orders; Surgeon-Lieutenant-Colonel J. Duke (Bengal), Medical Officer, Malwa Bhil Corps and of the Bhopawar Political Agency, to officiate as Residency Surgeon in Kashmir until further orders; Surgeon-Major R. J. Baker (Bombay), Residency Surgeon and *ex-officio* Assistant to the Political Resident in Turkish Arabia on return from leave to officiate as Medical Officer of the Malwa Bhil Corps and of the Bhopawar Political Agency until further orders; Surgeon-Captain R. H. Castor to be Civil Surgeon, Akyab, vice Surgeon-Captain Evans, transferred; Surgeon-Lieutenant Burnett to officiate in Medical Charge of the 26th Bombay Infantry until further orders; Surgeon-Lieutenant-Colonel Quill to the Medical Charge of the Station Hospital, Mhow, vice Brigade-Surgeon-Lieutenant-Colonel Moore, on leave on medical certificate; Surgeon-Major Hill to the Medical charge of the Station Hospital, Kirkee, vice Quill; Surgeon-Major Croly to the Medical Charge of the Station Hospital, Satara, vice Surgeon-Major Hill; Surgeon-Major Drury to the Medical Charge of the Station Hospital, Kamptee, vice Croly. Surgeon-Major-General William Roche Rice, C.S.I., Surgeon-General and Sanitary Commissioner with the Government of India, retires from the service.

NAVAL MEDICAL SERVICE.

Staff-Surgeon William Edwards Breton, M.D., has been promoted to the rank of Fleet-Surgeon in Her Majesty's Fleet.

The following appointments are notified:—Fleet-Surgeons: W. H. Stewart to Portsmouth Dockyard; George B. Murray to the Plymouth Division, Royal Marines; John Tyndall to the Haslar Hospital; Anthony Gorham to the *Royal Sovereign*; Thomas C. Hickey to the *Empress of India*; Alfred T. Corrie to the *Resolution*; E. R. H. Pollard to the *Excellent*; James L. Sweetnam to Sheerness Yard; and H. A. W. Richardson to the *Repulse*.

MILITIA MEDICAL STAFF CORPS.

Surgeon-Lieutenant A. R. Chater resigns his commission.

VOLUNTEER CORPS.

Artillery: 2nd Devonshire (Western Division, Royal Artillery): William Phayre Ryall, formerly Surgeon-Lieutenant, Army Medical Staff, to be Captain. *Rifle*: 2nd Volunteer Battalion, the Durham Light Infantry: Joseph Atkinson, Gent., to be Surgeon-Lieutenant.

THE SANITARY STATE OF BARRACKS.

We hear from time to time reports about the insanitary condition of our barracks and of the occasional outbreak of disease attributable to leaky drains. There is no doubt that many of our barrack buildings, especially in Ireland, are old, badly constructed, and badly drained. Quite recently Lord Stanley complained of the state of some of the London barracks, and notably of the Tower and Wellington Barracks. Mr. Campbell-Bannerman, who has of late assumed a humorous and even jocular tone in discussing Army matters, when recently discussing the Army Estimates said that if there was anything which he had served an apprenticeship to it was drains! The state of the drains in London barracks was a trifle, he declared, compared with that of his rooms at the Chief Secretary's Lodge, when he had the honour of being

chief secretary to the Lord-Lieutenant of Ireland. He did not deny, however, that the drains at the Tower were imperfect. The reconstructions which had taken place, although excellent in plan and design, had not been so perfectly carried out as they might have been. The main drains had been well laid, but the connexions were very defective and the defects would have to be remedied, and he gave an assurance to the House that the work would not be passed until it was approved by a competent sanitary engineer. As regards the Wellington Barracks, the War Minister stated that they were old barracks, and one could never be sure about the drainage of old barracks or old mansions; but he did not admit that the state of those barracks in this respect was bad; the health of the officers and men occupying them had been excellent. Apart from the skill and knowledge of the Royal Engineers the War Office had the services of an excellent and highly trained civilian sanitary expert. The subject of drainage is one about which most of us in civil life also have had some experience, and not always a happy experience. In the majority of instances defects and failure are not usually attributable to faulty plan and design, but to sins and defects of execution, in construction, work, and detail.

ARMY RECRUITING.

The Vicar of Old Ford in the east end of London has addressed a communication to the Chief Recruiting Staff Officer, St. George's Barracks, in reply to that officer's circular letter about obtaining good recruits for the army. The Vicar advocates a method which, in his opinion, would tend to remedy the deficiency of recruits and diminish the ranks of the unemployed, and lessen juvenile crime at the same time. Speaking from long experience he says that thousands of Board School children can obtain no employment when they leave their schools, and as the State and philanthropy have already to pay for their education and largely for their food and raiment, he would have the State adopt all unemployed boys of fourteen years of age and send them to large rural military camps or training ships, with the view of bringing them up to become our future soldiers and sailors. We have previously adverted to this proposal. There is no doubt that an enormous amount of good might be done in this direction among the ill-clad, ill-fed boys at present idling about our streets in want of employment, and the suggestion of turning this material to account for the benefit of the nation and of the boys themselves seems to us well worthy of consideration.

Whilst on the subject of recruiting we may here regretfully allude to the intelligence received of the death from cholera at Bangkok, Siam, of General the Hon. W. H. Fielding, who lately filled the post of Inspector-General of Recruiting at the Horse Guards.

REFRIGERATED BEEF.

Lieutenant-Colonel W. H. Allsopp, writing to the *United Service Gazette* referring to the 1895 edition of the "Manual of Military Cooking," expresses his surprise that refrigerated beef is now accepted for army service during ten months of the year, including June and July. He has been taught to believe, he says, that though this meat is mostly of excellent quality, yet through the action of the atmosphere in the summer months it is frequently bad on the surface, and is not suitable for the troops during the hot weather.

DEATHS IN THE SERVICES.

Surgeon Edward Alan Rogers, R.N., M.R.C.S., L.R.C.P. Lond., on the 4th inst., at the Royal Naval Hospital, Stonehouse. The deceased officer had been suffering from influenza.

Surgeon-Major Coates, M.D., late of the 26th Regiment, died on the 15th inst. at Summer Villa, Hythe, Kent, in his 69th year. The late officer entered the service in 1850, became Surgeon in 1856, Surgeon-Major in 1869, and after serving at Gibraltar retired on half-pay in October, 1881. He was also for some time medical officer to the School of Musketry at Hythe.

Surgeon-Lieutenant-Colonel W. L. Gubbins, acting for Brigade-Surgeon-Lieutenant-Colonel W. Taylor—on special employment in China—is confirmed in the appointment at the Headquarters of the Medical Department. Brigade-Surgeon-Lieutenant-Colonel Taylor will shortly be gazetted to the vacancy created by Surgeon-Colonel Gore's advancement.

"PLEURITIC EFFUSION WITH NEGATIVE PRESSURE IN THE PLEURA."

To the Editors of THE LANCET.

SIRS,—A considerable pleuritic effusion with a negative pressure in the pleura of four and a half inches of water which I described as "almost inexplicable" Dr. G. A. Sutherland apparently regards as nothing remarkable, and, indeed, easily explained. For the explanation he refers to the well-known fact that the pressure in a healthy pleural cavity is negative, and that the cause of the negative pressure is the elastic tension of the lung. He is very unfair to the teaching of the present day, and indeed to that of many years past, when he asserts that these elementary facts are not taught, or, as he seems to imply, are not even known to most of those who teach. He himself, however, fails to realise that the conditions in a pleura containing fluid are very different from those of health: that as the fluid increases in amount the negative pressure does not remain constant, but rapidly diminishes, until when the fluid has reached a certain size the pressure ceases to be negative and becomes *nil*, afterwards to become positive if the effusion still further increases; so that his explanation as applied to the case under consideration is not only no explanation, but is actually erroneous. The subject of pleural pressure has for some years been a favourite study of mine, and the more I see of it the more I find it full of difficulties. A few of these difficulties, with suggested explanations of some of them, he will find referred to in my Bradshawe Lecture on Pneumothorax for the year 1887. This, of course, he has not read, or he would not have suggested that I at any rate was ignorant of the elementary facts he speaks of. What we require is not a theory into which all facts must fit, whether they will or not, but clinical observations such as that I have recorded, by which any current theory may be tested, and upon which, if one theory be discredited, another may be built. Having a large number of such clinical facts at my command, and speaking from the experience of some years, I can only say that such a condition of things as a negative pressure of four and a half inches of water with a considerable and increasing effusion is of the greatest possible rarity. Whether the fact deserves to be on that account described as "almost inexplicable" is a matter of opinion. If Dr. Sutherland has other facts of a similar kind he would be doing science a service in bringing them forward, especially if he would, at the same time, provide a really satisfactory explanation of them.

I am, Sirs, yours faithfully,

Wimpole-street, W. March 25th, 1895.

SAMUEL WEST.

"PROVISION FOR YOUNG IMBECILES."

To the Editors of THE LANCET.

SIRS,—Your report in THE LANCET of March 23rd of what recently passed at the meeting of the Lancashire Asylums Board with regard to Poor-law provision for young imbeciles gives rise to the hope that something will at length be done in that populous county for this class in addition to the limited and fundamentally eleemosynary provision at the Royal Albert Asylum. But the question is one of considerable urgency in other counties than Lancashire—perhaps of greater urgency where there is not at hand an institution such as that just named. With the exception of that in the metropolitan district and the county of Northampton there is at present no specific provision in this country for the training of young pauper imbeciles at the cost of the rates. The counties of Middlesex, and I believe also Essex and Hants, are moving in the matter; but what is there to prevent the other counties of England and Wales from setting up, either separately or in combination, training institutions for improvable imbeciles? The Lunacy Act of 1890 gives power to any local authority, either alone or in combination with any similar authority, to provide separate asylums "for idiots, or patients suffering from any particular class of mental disorders"; and under this section (which it is to be regretted is optional and not compulsory) there need be no difficulty in doing throughout the kingdom all that is necessary for imbeciles, and even for epileptics whose mental

condition requires care. The further question of custodial provision for adult imbeciles, apart from lunatics, such as has been organised in the metropolitan district, is an after consideration; but the proper training of juvenile imbeciles would lessen the necessity for this provision, while its neglect is detrimental not only to the imbeciles themselves but to society at large. There is no doubt that the defective child if left to its own devices in too many cases becomes the delinquent man, and from the economical point of view judicious outlay for training would save expense in the end. The experience of the voluntary institutions is quite encouraging enough to justify this view, apart from the benevolent aspirations of Christian charity. If we measure ourselves by the standard of our Transatlantic cousins we shall find that we are considerably behind them in this matter. In America no less than seventeen States have established institutions for the "feeble-minded," their legislatures having voted "appropriations" for the purpose, in addition to several charitable foundations; and in these, and a few private schools no less than 6315 pupils are under training. If it be objected that America is a rich country we may turn to a comparatively poor one like Norway, where we shall find that three considerable institutions are maintained mainly by national funds. Is it too much to expect that England should also do her duty to her imbecile children?

I am, Sirs, yours faithfully,

G. E. SHUTTLEWORTH,

late Medical Superintendent, Royal Albert Asylum.
Richmond Hill, March 25th, 1895.

ROYAL MEDICAL BENEVOLENT COLLEGE.

To the Editors of THE LANCET.

SIRS,—You have taken such a warm and generous interest in the scheme for augmenting the annuities of the pensioners of Epsom College that I hasten to inform you that, in consequence of most generous assistance received under the will of the late Dr. Bowen of Melbourne, the council hope to be able to arrange that on and after July 1st the annuities of all non-resident pensioners will be raised to £30 per annum. To make this step actually secure in the future the council must impress upon the governors the necessity for continued and generous support. I may mention that the dividends accruing from your gift of £1000 have been continuously used to augment the annuities of existing pensioners.

The dinner this year will be held at the Queen's Hall, Langham-place, on Wednesday, May 15th, the Right Honourable A. J. Balfour, M.P., in the chair. I trust we may have the pleasure of including your names amongst the list of stewards, and we shall be glad to receive the names of any supporters of the College who will aid us at this festival.

I am, Sirs, yours faithfully,

C. HOLMAN, M.D., Treasurer.

37, Soho-square, W., March 25th, 1895.

"DEPRIVATION OF DEGREES."

To the Editors of THE LANCET.

SIRS,—In reference to the annotation in THE LANCET of March 23rd on "Deprivation of Degrees" by universities it may be of interest to state that the power referred to was not overlooked in the Charter of the University of Wales, issued in 1893. The 13th section of Article 14 provides that: "The [university] court may revoke the degree or degrees of any graduate of the university who shall be convicted within our United Kingdom or its dependencies of felony or of any indictable misdemeanour, and may restore on cause being shown any person whose degree has been revoked to the degree he previously enjoyed or to any lower degree in the same faculty without further examination."

I am, Sirs, yours faithfully,

March 23rd, 1895.

ISAMBARD OWEN.

"PARLIAMENT AND PRISON REFORM."

To the Editors of THE LANCET.

SIRS,—I think most of us who are interested in prison management are agreed that it is the aim of county councils to secure the government of prisons, as the magistrates had of yore; and, further, that the articles which appeared a short time back in a daily newspaper were written to attain this end. For my own part I suspect that the lengthy statement of your correspondent in THE LANCET of March 9th is

written for the same purpose. If this is so, his three columns of attack on the present administration of our prisons should be of no value; at any rate, your correspondent should be satisfied with the reply he has obtained from Dr. Quinton, of Wandsworth Prison. Dr. Quinton's very able letter points out the objections to your correspondent's charges of mal-administration, and it does so in a temperate manner, although it is evident that Dr. Quinton places little value on the credibility of this would-be prison reformer. It is so easy to raise an unwarranted scare on the question of treatment of our prisoners. Perhaps this is natural, they being shut out from the gaze of the public by high walls. But it does not seem right that public feeling should be so constantly harrowed by the public press as it has been of late. Any amount of what should be done for the reformation, &c., of prisoners can be said or written, but I believe, and I have had ten years of acquaintance with the criminal, that more is to be done towards lessening year by year the criminal population by outside work. Children born of criminal parents, and living in a thieves' locality, must almost of necessity become criminals, and it would seem that good, steady outside influences are at work if we portion out the late years' decrease in the prison population. Only a few points in your correspondent's statements, of which Dr. Quinton does not treat, I would touch upon—one, that if the dietary of prisoners is much improved the shorter sentences for local prisons will have to be increased in order to make prison life at all deterrent. As it is many men prefer to be in a prison than in a workhouse. That for a serious offence a flogging is by far a better punishment than a dietary one. It does not reduce the strength of the prisoner, and besides—a very important fact—it very greatly tends, at any rate for some months, to keep order in the prison.

It is not always remembered by writers that the inmates of a prison are largely made up of the scum of our population, ready for any disturbance if the government is lax, and lax prison management is not a kindness nor is it safe. Some years ago in my gaol in a fortnight four prisoners pretended to hang themselves in order to escape work. In each case as medical officer I informed the governor (now dead) that I believed that the prisoner was humbugging. Now, if he had sharply punished the first, at any rate the second, prisoner, the other cases would not have occurred, and a pretence at hanging may easily become a reality, therefore the practice is more serious than one of simply trying to get off work. When the fourth case occurred my medical treatment at resuscitation (the prisoner had nearly hanged himself beyond all earthly help) was such that there were no further pretences at hanging. But it was not my business to carry medical treatment to such an extent that it became a punishment, but it seemed a necessity, and I have always felt that the result justified me. Doubtless there would be great reason to feel that local prison life led to insanity if the whole two years of cellular imprisonment was the strict rule. But in no prisons do I expect is the strict letter of the law carried out. Hardly a prisoner is daily kept to his cell after the first year of a two years' sentence, although it is difficult in local prisons to find them work outside. The present Prison Commission, it may be hoped, will recommend a change of the law on this point. Your correspondent says "Punishment means solitary confinement in dark cells." He does not know that dark cells have been given up for many years. I remember taking a prison surgeon's work for some weeks at the time when country magistrates managed our prisons. Then three days in a dark cell was not an uncommon punishment. Your correspondent's "bureaucratic" Prison Commissioners have done away with the dark cell. He may be glad to know this.

I am, Sirs, yours faithfully,

PUGIN THORNTON.

Canterbury, March 23rd, 1895.

THE LATE LOUIS FLORENTIN CALMEIL.

To the Editors of THE LANCET.

SIRS.—In the admirably full and appreciative obituary notice of the famous alienist Calmeil, written by your Paris correspondent and published in THE LANCET of March 23rd, there is one point as to which it may not be out of place to say a word. Whilst vying with others to do honour to the memory of this great observer and worker we may rightly be careful lest, by inadvertence, we do injustice to another equally distinguished savant. In the latter

part of the notice it is said—and all will agree—that Calmeil's "name will for ever remain associated with the disease, 'general paralysis of the insane.'" But it is added that this disease "he succeeded in establishing as a clinical and pathological entity." He, indeed, gave to the motor aspect precisely the name which, transferred to the disease in its entirety, has perhaps survived more than has any other of the numerous names which have been applied to the disease. And on the basis of the quotations made at the beginning of the notice (if we accepted them) the latter part of the above statement would hold good. Nevertheless, it is the fact that the work of establishing that which was subsequently known as "general paralysis" as a clinical and pathological entity (as so many have held it to be) was first accomplished by Bayle. In my work on the subject, after mentioning the partial clinical descriptions of some previous observers, I briefly referred to the relative position of Bayle and Calmeil in the discovery of "general paralysis," and in the following words: "The discovery was completed by Bayle (1822, 1825, 1826), who gave the first full account of the affection, and who was closely followed by Calmeil (1826) in this investigation." Here Bayle's three contributions are taken as a connected series, constituting the first full account. It would trench far too much on your space and my time to add here proofs for the words just cited. Looking at the state of medical knowledge in general and of that of mental disease in particular at the time, and the early age (twenty-eight) at which he published the book, one must deeply feel very great admiration for the clinical acumen and pathological knowledge shown by Calmeil in his early work on this subject.—I am, Sirs, yours faithfully,

W. JULIUS MICKLE.

Grove Hall Asylum, London, March 25th, 1895.

"COLOUR VISION AND ACCIDENTS."

To the Editors of THE LANCET.

SIRS.—In reply to Dr. Gowers' question in your issue of March 2nd, "Has any accident been brought home to defect in colour vision?" will you allow me to call attention to several instances showing positive evidence on this point quoted by Dr. Edridge Green in his book on "Colour Blindness" (p. 224 *et seq.*)? He states that "there are many accidents in which the cause has been definitely proved to be colour blindness," and refers to the following cases in point.

1. A colour-blind man, who stated that his steamboat had collided with and sunk a steamboat on account of his inability to distinguish the signal lights.¹
2. The case of the pilot of the steamer *City of Austria*, which was lost in the harbour of Fernandina, Florida, in April, 1881. He was proved to be colour-blind, "and it would appear that he mistook the buoys, and his mistake cost the owners \$200,000."²
3. Related by Dr. Joy Jeffries. An accident between Helsingfors and Tavasthus, July, 1876. "It was caused by a colour-blind switch-tender showing a green instead of a red light to the approaching train."³
4. A railway collision due, according to his mate, to the colour blindness of an engine driver.⁴
5. A railway collision in consequence of a train over-running a signal. The driver was colour-blind and "believed that his sight was the cause of the accident."⁴
6. A railway accident due to the engine driver's inability to distinguish the red light.⁵ The last case was one of acquired colour defect, and Case 2 was diagnosed as one of tobacco amblyopia.

Captain Abney, in his recently published Tyndall Lectures on Colour Vision, says (p. 167), with regard to the loss of life owing to colour blindness: "The evidence is, as a rule, merely negative, though there are cases extant where great losses which have occurred can be traced to a deficiency in colour perception." The cases quoted prove, I think, that there is positive evidence of the disastrous results which may arise from defects for colours. Possibly there are degrees of deficient colour perception quite compatible with safety in those whose duty requires them to recognise coloured signals, but where the boundary between "safe" and "dangerous" lies must be a most difficult problem to solve.

I am, Sirs, yours faithfully,

WALTER W. SINCLAIR, M.B.

Ipswich, March 26th, 1895.

⁵ Mr. Haynes Walton, in the Times, Jan. 3rd, 1877.

"THE LONDON AND MANCHESTER INDUSTRIAL ASSURANCE COMPANY, LIMITED"

To the Editors of THE LANCET.

SIRS,—Our attention having been called to an article in your issue of the 23rd inst. concerning this company, we beg that you will be good enough to insert this response in your next issue. We emphatically deny your allegation that we "make profits out of the sweating of medical men who voluntarily sell themselves into bondage," for we sweat no one, and there are no professional men less fettered than those who attend our policy-holders in time of sickness. "Provident dispensaries," you say, "are all very well, being in the nature of charity," but we are endeavouring, and for no unworthy or sordid motives, for our shareholders derive no pecuniary benefit from our medical aid branch, to do something for those in whose ears the word "charity" in such a matter is synonymous with degradation and reproach, and to inculcate self-help, self-respect, and thrift in others. This scarcely deserves the appellation of "touting," as some understand the meaning of the word. Our members are, in fact, very largely composed of those who would have, did not the company collect their contributions in a small weekly sum, to seek hospital or dispensary advice, or failing that run up doctors' bills which their meagre incomes would never, unfortunately, permit them to pay. How often one hears it said that medical men are the first that people think of calling in, and the last they think of paying! The fact is, however, that in nearly every instance it is inability and not indisposition to pay. Such persons and the medical profession at the same time are assisted by this company's system. On the question of payment to our medical officers we have no hesitation in saying that they are as well remunerated by us as by their private practice amongst the same class of people. Our payments to them are higher than they appear on the surface, because we pay for all members on the quarterly lists supplied (in advance) by us, whether the members continue paying or lapse out during the quarter, as many do from one cause and another, and in which latter event they cannot apply for medical attendance. We claim, and most justly, that this company, far from doing a pecuniary injury to the medical profession, assists it very much indeed.

I am, Sirs, yours faithfully,
W. WOODWARD.

Managing Director, London and Manchester Industrial Assurance Company, Limited.
Southwark Exchange, London, S.E., March 27th, 1895.

To the Editors of THE LANCET.

SIRS,—Your annotation on the above in your last issue points out most clearly the nature of this commercial undertaking and medical sweating, and it ought to be the means of dispersing the array of medical men's names from the list which the touters for this company pride themselves upon when pestering the patients of other medical men when already in attendance. Let insurance companies canvass for their own legitimate business, but not for medical attendance and medicine. It may be all very well for young practitioners to work for literally nothing in order to get patients; but their association with this company does incalculable injury to their fellow-practitioners and spoils the public. I know of a case of a man in receipt of at least £3 per week owing his medical attendant a small bill for fees proportionate to his earnings, and when payment was sought was informed that he had joined the above company. This is simply disgraceful. In your annotation you say, "Provident dispensaries are all very well, being in the nature of charity." All are agreed upon that, but let them be properly organised and fairly conducted. Should charitable dispensaries conduct provident work (semi-charity) with a restricted medical staff? Ought not a provident dispensary be a self-supporting institution, open to all medical men residing in the neighbourhood to take a part? Abuses such as these require the remedy—viz., the staunch and deliberate action of individual members of the profession to safeguard their interests which are at stake and disassociate themselves from that which is an evil in our midst.

I am, Sirs, yours faithfully,

March 27th, 1895.

INQUIREE.

To the Editors of THE LANCET.

SIRS,—I fear that "A General Practitioner" is not fully aware of the power of the so-called medical aid societies or

of the way the medical profession is getting entangled in the meshes of their ever-spreading net. The lower middle and working class practices in most towns, it seems to me, are gradually being absorbed by those societies. In this town almost every man, woman, and child belongs to one or another of them. The fees collected are 1d. per week under twelve years of age and 1d. over that age, of which 25 per cent. is retained by the society. One or two points must be considered. The societies have obtained so much influence that it is a necessity to allow one's name to be on the list of medical officers or lose the publicity which others enjoy. Again, it is absolutely necessary under existing conditions for some men in the place to undertake the work, or the experiences of the Cork practitioners would be repeated. Could these societies be stopped the congested state of the profession would be much relieved, as so many more men could get a comfortable living among the same number of inhabitants were the fees reasonable. A less drastic method would be to insist on the clubs revising their fees, and charging at least 3d. a week per member. Compared with the present remuneration offered by these clubs, the fees of 1s. and 1s. 6d. condemned by the South-West London Medical Society would be generous, for twenty consultations a day at 1s 6d. would exceed £545 a year, even admitting that none of the patients could afford more. At the present rates, to get the same income (allowing two children to one adult) it would require over 5000 members, and I leave it to those who have experience in this class of work to decide which sort of practice would be the more lucrative. It is difficult to suggest a remedy, but I believe that if men who unwillingly hold these cheap clubs would keep a strict account of one year's work and publish it, with the remuneration received, and point out to the public the absurdity of expecting conscientious treatment and necessary drugs for the price, the evil would remedy itself.

I am, Sirs, yours faithfully,

March 27th, 1895.

AN UNWILLING CLUB DOCTOR.

To the Editors of THE LANCET.

SIRS,—As one of the medical men attached to the London and Manchester Industrial Assurance Company I was shocked to read the letters in THE LANCET of March 23rd, along with your annotation commenting on the subject. Some months ago I was approached by representatives of this company with a request that I should become one of their medical referees. This I lightly undertook, the more so on seeing well-known names with high medical qualifications on the list they supplied. Some of those had for twenty years done the work, so it was reasonable to presume that the company's methods were beyond reproach. Their agents assured me that there was no desire to push the medical side of the business, but on the contrary, they would rather be without it, and that no touting of the patients of other medical men took place; in fact, that assurance work was what was desired, and the persons assured were themselves the applicants for entrance into the medical department. Of late I have not been satisfied that such is the case. Patients have come for advice &c. who were quite able to pay a reasonable fee, and such I have refused to treat as members. I have now sent in my resignation as one of the so-called medical referees, and I am sure that such will be the course adopted by many who like myself now find that touting has been carried on without their sanction.

March 23rd, 1895.

I am, Sirs, yours faithfully,

NEMO.

"THE TITLE OF 'DOCTOR.'"

To the Editors of THE LANCET.

SIRS,—I see that you have once more opened your columns to this chronic discussion, and have allowed Dr. Black to write fully from his point of view. Therefore I presume you do not bar the other side of the question. I have repeatedly applied to the Royal College of Physicians of Edinburgh on this matter, and have always received the reply that my legal title as Licentiate was that of "Physician," and that, while disapproving, the College could not disallow the Members and Licentiates using the title "Doctor" if they chose to do so. In effect, the title of "Doctor" as applied to medical men is a courtesy title, given by custom, and adopted in consequence of custom. If it be true that it is a courtesy title then those who withhold it on technical grounds are not courteous. I believe that legally a Licentiate of a medical

college has quite as much right to use the title "Doctor" as a layman has to use that of "Mr.," and much more than that of "Esquire," which, strictly speaking, should be reserved to a distinct class. The matter, then, is practically one of "taste," not of "law," and "de gustibus non est disputandum." Underlying this petty and trivial squabble as to little dignities of title is, however, a matter of more importance; in fact, the only important thing to my mind in the question at all. It is an index of the miserable jealousy and throat-cutting spirit which permeates the profession. Twenty qualifying bodies carry on a "battle of the shops," some of them actually pulling their degrees as superior articles to diplomas. Who can wonder that with so arrogant an *alma mater* the often half-educated graduate starts in life with an exaggerated idea of his own importance as a "university man" and complains bitterly of any practitioner who styles himself "Dr.," in fear that his brand-new "brass" M.D. should not look large enough by comparison?

If all M.D.'s were university men in the true sense, if they had graduated in arts instead of passing a very ordinary preliminary, if their science training had been very much wider and deeper than ours, we might allow them some distinction besides that of putting their university degrees after their names, and where they came from. But, Sirs, we know very well it is not so; we know that the medical section of a university is often merely a medical school, with which our great teaching hospital schools of London would in many respects compare favourably. The difference is this, that by schools being affiliated to a university degrees can be obtained after an ordinary curriculum and ordinary examinations in some cities, while in London this is not the case. The true remedy for this anomalous state of things appears to be that all medical titles should be assimilated in form, the only distinction being the status of the school from which they are obtained, or that the one portal system for each division of the country should be adopted. In the meantime I usually find the most eminent and best-qualified men of my acquaintance invariably giving the courtesy title, and except as a matter of abstract justice feel perfectly indifferent on the vexed question of "Dr. versus Mr." If Dr. Black is willing to pay the costs he will find scores of instances in which the title of "Doctor" is assumed by M.B.'s and College of Physicians diplomates against whom legal proceedings might be taken with a view to restrain their infringement of the supposed right of that varying quantity, a real "M.D.," or possibly satisfaction might be obtained by obtaining the opinion of counsel. I fear Dr. Black would find that—as in the title of "Reverend"—in matters of taste, courtesy, and custom, these, and not law, will rule.

I am, Sirs, yours obediently,

Loughborough, March 16th, 1895.

J. B. PIKE.

To the Editors of THE LANCET.

SIRS.—I have read with interest the letter in THE LANCET of March 16th from Dr. Campbell Black, and, whilst entirely agreeing with him that assuming the title of "Doctor" without a degree entitling one to it should be considered "infamous conduct in a professional respect," I cannot agree with him as to the deception practised on the public. Does he mean to imply that unless one is an M.D. he is not a doctor? Does he mean to imply that M.D.'s are the only people capable of "doctoring"? If so he errs greatly. Are M.D.'s so skilful, so learned, so very much superior that they should receive a title, whilst men with only from one to six diplomas, who have spent exactly the same time in the study of medicine as themselves, who have seen the same operations, the same patients, and attended the same lectures, are to have no distinction of this sort? What is an M.D. but a diploma a very little better than other diplomas? Why are there not more M.D.'s? Is it because men are not able to pass the examinations? No, certainly not; often it is because they cannot afford to attend a university, often simply because they make a false start, and, as it were, get off the "main line" and have to travel along a track which does not lead to an M.D. I would suggest a remedy. Let all M.D.'s be called physicians and ordinary diplomates doctors; for, whatever our qualifications, we are doctors—why should we not be allowed to say so? I think the deception on the public, if any, is on the part of the M.D. who tells them that he alone is a "proper doctor," and gives the public to understand that this is not the case with

his neighbour who only happens to be, say, F.R.C.S. Eng., L.R.C.P. Lond., D.P.H. In conclusion, I would point out to Dr. Black what he appears to have rather overlooked—viz., the most eminent men in our profession are not all M.D.'s. Are our great surgeons to have no title, whilst some clumsy bookworm who has managed to scrape through the M.D. poses before the public as a greater man? I do not myself want to be called "Doctor" except to prevent people saying I am not one. I should prefer to see the title done away with entirely.—I am, Sirs, yours faithfully,

March 22nd, 1895.

M.R.C.S. &c.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Assizes.

LORD CHIEF JUSTICE RUSSELL concluded the criminal business of the Assizes on the 25th inst. No conviction for murder has occurred, but in one case in which a man was charged with the murder of his wife the judge told him that he had had a very narrow escape. The medical witness found thirteen of the woman's ribs broken, some of the fragments having penetrated the lungs. It was a sad story of intemperance on the wife's part, followed by brutality on the part of the husband, ending fatally. A woman, who had been convicted of causing grievous bodily harm to a girl entrusted to her care, was sentenced to five years' penal servitude. The evidence disclosed acts of fiendish cruelty, the prisoner having on several occasions burnt and beaten the child, who, unable to bear it any longer, escaped to a neighbour's house. Severe punishments were also awarded to those who had been convicted of wounding with knives and to those who had been found guilty of criminal assaults upon children.

The Head Constable's Annual Report: Decrease in Drunkenness.

Captain Nott-Bower's annual report shows a most gratifying diminution in the number of cases of drunkenness. Making every allowance for the old objection to statistics that they may be made to prove anything, there is one circumstance which goes far to prove the truthfulness of these. Up till 1893 the statistics had to be made up to the end of September in each year; those of 1893 and 1894 relate to the whole of each respective year only. Again, the statistics of each year have always been (with the exception mentioned) on the same plan. Up till 1889 the yearly number of cases had been as high as 21,694 and never lower than 12,568. The following are the numbers for six years: 1889, 16,042; 1890, 14,680; 1891, 11,343; 1892, 9005; 1893, 7936; 1894, 5657. There is nothing after all that is inexplicable in such a reduction. For years past Liverpool has been reviled as "the black spot on the Mersey"; while judges, magistrates, clergy, and philanthropists have all raised their voices in the cause of temperance and in denunciation of drunkenness. It would, indeed, be disastrous if all these efforts had been in vain. But two more circumstances must be taken into account. One is that a large number of persons are yearly being absorbed into the ranks of adult citizens who have been brought up to be total abstainers from childhood, a number which is yearly increasing. Another is that the times have been very depressed for some years past, and if prosperity shows itself in an increased revenue from the sale of intoxicants it is, too, probable that reduced wages and loss of work mean less drink and less drunkenness.

The Effects of Punishment on Drunkards.

In connexion with this subject it must be borne in mind that the penalty of spending a night—possibly two nights—in the case of those arrested on Saturday in Bridewell is calculated to act as a deterrent against the repetition of the offence. While a total of 3800 persons were apprehended for the first time, those who had made one previous appearance only numbered 644, the hardened offenders decreasing gradually down to the twelfth time, when they showed a tendency to rise again. This accords with the views of experienced magistrates, who have expressed the opinion that a large number of persons charged with drunkenness come before the bench once, and once only.

The Report on Immorality.

With regard to the second great sin of great cities the head constable's report is less satisfactory. During the

year 1894 proceedings were taken in 792 cases against persons for keeping brothels; in 677 a conviction followed, 32 were discharged, and in 83 the persons charged absconded. But in 13 cases only did there appear to be even *prima-facie* evidence against the owners or agents of these brothels of an offence against the letter of the present law. The 13 cases when tried resulted in only 2 convictions, both these convictions being against the same woman, who was convicted mainly on evidence that she was the habitual frequenter of the brothels of which she was owner. It is incredible that there can be such ignorance on the part of owners and agents as to the uses to which their houses are put.

The late Distress during the Severe Weather.

The employment of the police, both city and county, as almoners during the severe frost and the distress which prevailed through so many men being thrown out of work was attended with the happiest results. As a local paper observes, it presents the police in a new and honourable phase. In times past they were regarded almost as the natural enemies of the lower classes; they are now recognised as their best friends. House-to-house visits were made, and by this means, combined with kindly tact, many deserving poor, who would rather have starved than have asked for help, were relieved from hunger, being provided with food and fuel. This was in addition to the more clamorous being also relieved. In a suburb largely inhabited by the working classes 23,016 meals and 46 tons of coal were distributed; the donations in money amounted to £282, but the contributions of food, coal, and clothing were also so liberal that there remains a substantial balance for any future emergency.

March 26th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Aberdeen University.

DR. MACGREGOR has handed over to the University Court the sum of £300 subscribed towards the "Dr. James Anderson Memorial Fund." It is to be devoted to instituting a gold medal and, if possible, a prize for clinical medicine, to be awarded annually. It has been competed for this year for the first time, and has been won by Mr. Robb. The extension scheme of the University buildings has assumed a new phase within the last few weeks. The side wings of the quadrangle at Marischal College are to be completed, but the front block, which was to be largely the administrative block, is to be for the present abandoned. Towards this new plan Dr. Mitchell of Newcastle has offered another £4000 on certain conditions.

The Scientific Study of the Mental and Physical Conditions of Children.

On March 25th a large audience assembled in the Natural History class-room in Marischal College to hear Dr. Francis Warner lecture on this subject. Principal Sir William Geddes occupied the chair, and, besides a number of the professors, the audience included the chairman and several members of the Aberdeen School Board, the Rector of the Grammar School, and many teachers.

Death of Miss C. S. A. Peddie.

Miss C. S. A. Peddie (Sister Sibbald) died suddenly on Wednesday, the 20th inst., at King's College Hospital, from pulmonary embolism ten days after an operation. She was a daughter of Dr. Alexander Peddie of Edinburgh, and had been eleven years at King's College Hospital, four as ward sister and seven as home sister. After a service in the chapel at King's College Hospital on Monday last, the remains were removed to Edinburgh and interred on Tuesday morning. Miss Peddie was beloved by a large number of friends in London and Edinburgh, and much sympathy is felt for the family in their sad affliction.

At the February meeting of the Aberdeen Branch of the British Medical Association a motion by Professor Ogston to contribute 20 guineas towards the Aberdeen University Extension Scheme was unanimously adopted. At the March meeting a similar motion by Dr. Garden to give another 20 guineas to the Aberdeen Royal Infirmary was negatived.

March 27th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Richmond Lunatic Asylum.

IN THE LANCET of the 16th inst. notice is taken of the grant by order of council of £6000 to complete the erection of temporary buildings provided to meet the overcrowded condition of the asylum, and to provide additional accommodation at Portrane pending the erection of a special lunatic asylum there. The latter will cost between £200,000 and £300,000, and much excitement has been caused by articles and correspondence in some of the daily journals in favour of the acceptance of the lowest of three estimates tendered by three architects whose designs were approved of by the inspection committee and classed together as of equal merit. The question has now been settled, for the board of control of the Irish lunatic asylums has selected the design of the eminent architect, Mr. George Ashlin.

Poor-law Medical Officers.

The *Irish Times*, in an excellent leading article on the subject of the election of Poor-law medical officers by boards of guardians in Ireland, complains of the absence of that "proper chance of promotion" which would secure for the most populous and important districts those who possess the largest knowledge and the best repute. The editorial remarks seem to be worthy of reproduction, as they advocate to a certain extent that fixity of tenure in these posts upon the want of which THE LANCET has frequently commented. Nothing, it is stated, is more inimical to the public interest than the fixing for the greater part of his useful life of a man of acknowledged mark and eminence in his profession in a place where there is no demand for his powers, while at the same time in other quarters men of shorter standing, who have yet their fame to make, may be put in charge of districts where the severity of the duties and its higher responsibilities are manifest.

Influenza in Dublin.

Owing to the prevalence of this disease the number of deaths in Dublin has recently far exceeded the average of this somewhat unhealthy town. Teaching at some of the medical schools here was almost brought to a standstill on account of the illness of professors and lecturers. The disease proved indirectly fatal to a member of the family of one of our best-known and most popular surgeons, Mr. Meldon, Ex-President of the Royal College of Surgeons in Ireland, and much sympathy is felt for him in his bereavement.

Health of Dublin.

Sir Charles Cameron reported that during the week ending March 16th the death-rate in the whole area was 41.9 per 1000, the rate in the city being 47.4. During the last three weeks the death-rate, which was previously below the mean, rose to figures considerably above the average for the corresponding period in the previous ten years. In the English and Scotch towns very high death-rates prevailed, and from an earlier period in the year influenza was more or less responsible for the increase. As that disease has only appeared in Dublin when it was beginning to decline in England, and when the weather everywhere had become mild, it may be hoped that it has reached its maximum here, and that its fatality will henceforth decline.

The Influenza Epidemic in Belfast.

During the past three weeks there has been a very widespread epidemic of influenza in Belfast and throughout the north of Ireland. Though a large number have been attacked the disease on the whole has not been so severe as in the previous visitations. Infants and children have suffered in larger numbers than formerly, and a red rash has been frequently an accompaniment of the disease. In certain cases the rash has been attended with itching like urticaria, while in others it has been scarlatiniform. It is not followed by desquamation, and in the early stages the diagnosis from true scarlet fever has sometimes been difficult.

The Winter Session, Belfast.

The winter session will terminate on April 11th. Among many of the teachers the feeling is growing that it would be better to begin earlier, say in the middle of October, and to end at the termination of March. It is also hoped that the examinations of the Royal University of Ireland (to which the Belfast school sends over 50 per cent. of the candidates) will

also be held at an earlier date. At present the M.B. examinations take place in May, and as the summer session in the schools begins on May 1st these arrangements of the Royal University interfere with teaching in the case of those who are examiners. There is no reason at all why the examinations should not, as in some other universities, be in April.

Belfast Ophthalmic Hospital.

Dr. Walton Browne, in presenting the surgical report at the annual meeting of this hospital on March 25th, said that during the past year 1212 eye cases, 220 ear, and 230 throat cases were treated at the extern department, and 109 cases were admitted into hospital. During the year the assistant surgeon, Dr. Calwell, resigned, and Dr. Cecil Shaw was appointed in his place. A large number of students attended the clinique. Financially there was a balance in favour of the institution.

Witchcraft in Clonmel.

A most extraordinary case is reported from the neighbourhood of Clonmel, and it has caused a most painful shock to the whole community, especially as it indicates that there are some few people who believe in the powers of witchcraft. It appears a poor woman named Cleary was visited by the dispensary medical man, who found her suffering from nervous excitement and a slight attack of bronchitis, but there was nothing to cause anxiety. Later on some of her friends apparently conceived the idea that the real Mrs. Cleary had been spirited away and a witch substituted in her place. A "herb doctor" was called in, but the poor woman strenuously objected to swallow his potions, and her obstinacy was regarded as a further indication that the real Mrs. Cleary was not being dealt with, and with the view of ascertaining the truth the poor creature was actually placed across the fire. It was stated that soon afterwards she left the house, and for a time no tidings of her could be found. Eventually, however, the police, after careful searching, discovered her body buried in a field. An inquest was held, and the evidence of the medical men who made the post-mortem examination is most gruesome reading. The right hip and thigh and a portion of the abdomen were charred and burned, with the internal organs protruding through the burned apertures. The jury brought in a verdict that death resulted from burns, and a magisterial investigation into all the circumstances is being held. The inspector of police states in an information that he has reason to believe that it was by the instructions of the "herb doctor" the horrible injuries were inflicted.

The President of Queen's College, Galway.

The Queen has been pleased, on the advice of the Government, to withdraw the warrant that terminated Dr. Moffett's appointments in Galway on the 25th inst. Dr. Moffett will continue to hold his office as before.

The Battle of the Clubs at Cork.

The following subscriptions are announced by Mr. D. D. Donovan, the hon. treasurer of the Cork Societies Medical Officers' Indemnity Fund:—Mr. Henry Stear (Saffron Walden, Essex). £1 1s.; Mr. T. Jenner Verrall (Brighton), £1 1s.; Surgeon-Major R. T. Beamish (The Citadel, Portland), £2 2s.; Lincolnshire Division, Midland Branch, British Medical Association, £4 5s.

The Condition of the Bishop of Cork.

I regret to say that I have learned through a most reliable source that the Right Reverend Bishop Meade has been bitten by a dog which at the time exhibited symptoms which would indicate that it was possibly suffering from rabies. The Bishop, noticing that the dog was ill, stooped down to fondle it and was bitten slightly on the hand. The coachman then endeavoured to remove the animal, and in the attempt had his hand very severely lacerated. Further investigation showed that the dog was suffering from paralysis, and as he was not running about in the usual frantic fashion peculiar to rabid animals it does not appear to have occurred to his lordship that there might be any special danger attending the bite, and he allowed five days to elapse before he consulted a surgeon. The dog, which was of the terrier breed, was afterwards sent to a veterinary surgeon, and he, fearing it was suffering from the paralytic variety of rabies, recommended its destruction, and the spinal cord has been submitted to a pathologist for examination. It is stated that his lordship and the coachman have proceeded to Paris to put themselves under the Pasteur treatment. General sympathy is felt throughout the city for the Bishop, as he has become very popular since his arrival in Cork

owing to the active interest he has taken in many works of public utility. He has been a prominent figure, too, at the board meetings of some of our more important medical charities.

The Death-rate in Cork.

The medical superintendent officer of health reports that for the four weeks ending March 9th the mortality was 36.75 per thousand and he attributes the high rate to "the depressing influence exercised by the recent cold weather and to the long-continued prevalence of easterly winds." It seems strange that though the general mortality was so high the number of infectious cases showed a very considerable decrease as compared with the number in the corresponding period of last year, and, as I mentioned in my last letter, the amount of sickness of any kind has been very small.

Mr. Richard Murphy, the medical officer, Newbridge Dispensary, county Kildare, died on the 24th inst.

March 26th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Reorganisation of the Paris Maternity Hospital.

Up to Jan. 1st, 1895, the Maternité or Maison École d'Accouchement, situated in the Boulevard de Port Royal and containing 322 beds, occupied an exceptional position amongst the hospitals of Paris. Instead of being superintended by an accoucheur it was directed by a surgeon (Dr. Guéniot), although the practical working of the establishment was in the hands of Madame Henry, the *sage-femme en chef*. Taking advantage of the retirement through age of Dr. Guéniot, a change was made in the organisation, Dr. Budin, the well-known physician-accoucheur of the Charité, being appointed accoucheur, with Dr. Auvard as assistant accoucheur, Dr. Charrin being appointed in charge of the patients needing ordinary medical care. The accoucheur has to deliver eighty lectures per annum, the physician twenty, and the assistant accoucheur forty. The *sage-femme en chef* will take part in the teaching of the female students (*élèves sages femmes*). We thus see a decided anomaly removed, and a lying-in establishment provided for the instruction of female midwives placed, as it should be, under obstetric physicians.

Sanitaria for Phthisical Patients.

It has long been a matter of surprise to Englishmen that there should exist in such an enlightened city as Paris no hospital devoted to the treatment of phthisical patients. As a matter of fact, the medical wards of the general hospitals are filled with these poor sufferers, who, being in a great majority (an average of about 200 of them die weekly in Paris), monopolise room sadly wanted for men and women affected with other diseases. The danger of infection incurred by the neighbours of the *poitrinaires* is too obvious to be mentioned. There has recently been formed the Société des Sanatoria Français with the object of establishing in different parts of the country retreats for cases of phthisis. The society is already at work, for land has been bought in the neighbourhood of Ajaccio, the capital of Corsica. Here three sanatoria—one maritime, one at an elevation of 1000 metres, and one situated still higher (1600 metres)—will soon be built. The mayor of the town, fearing that the presence of these establishments would constitute a standing danger to the population of Ajaccio, consulted Professor Verneuil, President of the Œuvre de la Tuberculose, and Professor Brouardel, President of the Comité d'Hygiène of France. Dr. Petit, secretary of the Œuvre, was despatched to Ajaccio to inspect the *locus*, and he has reported in favour of the innocuity of the proposed sanatoria. The Société des Sanatoria Français intends to construct pavilions in different towns for the reception of phthisical patients, whose keep and treatment will be paid for by the local Assistance Publique. Dr. Netter has also investigated the question of the danger attending the hospitalisation of this class of patients, and he reports to the Comité Consultatif d'Hygiène that the observance of ordinary sanitary rules will largely suffice to obviate any risk incurred by the inhabitants of towns in the neighbourhood of such establishments.

A Health Exhibition.

Paris is to have its "Healtheries," the scene to be the Champ de Mars, and it will be held from May 15th to Sept. 15th. The exhibits will be divided into ten classes—

viz., Hygiène de l'Habitation Privée et Collective, Hygiène Urbaine, Prophylaxie des Maladies Transmissibles, Démographie et Statistiques Sanitaires, Science Sanitaire, Hygiène de l'Enfance, Hygiène Industrielle et Professionnelle, Hygiène Alimentaire, Hygiène du Vêtement, and Exercices Physiques.

The Transmissibility of Tuberculosis.

Dr. Rémy¹ relates a case of tuberculous inoculation, the victim being a healthy child aged three years. The child had a wound of the chin occasioned by a fall. This wound became the seat of a warty cutaneous tuberculous growth, whose presence caused the development of tuberculous lymphangitis of the neck, resulting in the formation of an abscess. The origin of the infection may have been due to kisses of a tuberculous person.

March 26th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Vienna Medical Society: Syphilis; a Case of Raynaud's Disease.

PROFESSOR NEUMANN, at a recent meeting of the Vienna Medical Society, spoke on syphilis of the internal female genitals. Concerning recent exanthemata on the vaginal mucous membrane, he said venereal eruptions have not been satisfactorily ascertained to occur there or on the cervix uteri, with the exception of moistening papule. In 100 cases of syphilitic primary diseases fifty-one have appeared on the vaginal portion of the cervix and only four on the vagina; they caused cicatrised strictures and menstrual interruptions. Gummatous nodes and formation of ulcers on the internal female sexual organs have been proved by numerous observations without doubt. The syphiloma of the vagina occur at the orifice and the anterior, rarely in the middle third. He had observed a diffusive gummatous affection of the vagina resulting in recto-vaginal fistula. Syphilis of the corpus uteri is extremely rare, but metritis and endometritis frequently cause abortion or premature birth. By means of statistical returns Professor Neumann showed the pernicious influence of syphilis on posterity. Concerning the death of the foetus from syphilis, infection of the ovum or the semen has been suggested; but syphilitic disease of the endometrium and placenta sufficiently explains a great many cases of habitual abortion. By the blood exchange taking place between the foetus (affected with syphilis from the father) and the mother the uterus must be attacked. It is furthermore known that syphilis localises itself on parts which are often irritated. This is the case with the uterus. Cases not uncommonly occur in which the mature foetus is stillborn or dies soon after birth without any syphilitic symptoms descending from sound parents, whereas parents affected with tertiary syphilis procreate sound children. Without doubt anæmia and the decrease of the red blood-corpuscles and the hæmoglobin resulting from it perniciously influence the life of the foetus. Dr. Narath, assistant of Professor Gussenbauer, exhibited a patient aged forty-four years who shows the typical symptoms of Raynaud's disease. Both hands and feet were cyanotic, the skin arid and exfoliating, and the fingers cylindrical and symmetrically shortened by gangrenous processes. Dr. Narath supposes it to be an idiopathic disease in consequence of functional or anatomical lesions of the bloodvessels. The idiopathic form is characterised by the appearance of paronychia, and the symptomatic by gangrene in little patches. Professor Drasche has observed a similar case in consequence of influenza, therefore he supposes an infectious origin of many cases.

Anthropological Society.

At the last meeting of this society Professor Benedikt spoke of the cranium and brain of the murderer Schneider, whose name still frightens the housemaids of Vienna. The cranium is extremely asymmetrical and the sutures are grown together. On the brain Professor Benedikt clearly saw the middle furrow of Larrey, which characterises the brain of the beasts of prey. Schneider was not diseased in mind; he had a congenital and developed criminal nature, and the treatment of such a perversion is the task of justice. The removal of creatures who injure society by their qualities is the right of the law. Professor Neumann publishes a peculiar case of parasitic disease of the skin. The

parasite produced burrows in the skin, and when these are in process of formation the patient passes sleepless nights in consequence of terrible pains. In the present case the burrows are on the nates and the leg. Professor Neumann observed the course of development of a burrow. First arises a reddish place of the extent of a thaler; then in the middle of it a white spot appears, which grows red in half an hour or so. The animal lays eggs under the skin; from these grubs originate, which produce the burrows.

March 24th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

The Whipping-post.

THE subject of instituting the whipping-post as a method of punishment of those who inflict injuries upon their victims was discussed in the Section on Public Health of the Academy of Medicine. It was brought forward by the President of the Society for the Prevention of Cruelty to Children, who had prepared the form of a law to be introduced into the Legislature. The argument for the measure was that the only punishment which criminals guilty of felonies against the person fear is pain, and hence flogging will accomplish far more in deterring this class than imprisonment. It was contended that the corporal punishment should not take the place of imprisonment, but should be additional to that at the discretion of the court. The proposition was favourably received by some of the medical members present, but it has not been approved by the profession at large. Nevertheless, the measure has been introduced into the Legislature, and has been commented upon more or less unfavourably by the public generally. There is little doubt that it will be rejected.

Large Endowment of a Medical School.

The oldest medical college in New York, and the second oldest in the United States, the College of Physicians and Surgeons, has been the recipient of large endowment funds from the Vanderbilt estates. The Senior Vanderbilt gave \$500,000 towards the purchase of a new site and the erection of buildings several years since. This was followed by several smaller gifts from different members of the family. With these means at its command the trustees greatly enlarged and improved their facilities for teaching. Large and well-equipped laboratories were established, clinical instruction was perfected, and as a consequence the classes rapidly increased until it became impossible adequately to provide for them. And now the Vanderbilts have duplicated their endowment, and the College will at once extend all its departments of teaching. When the institution has completed all its projected improvements, the "Old School," as it is familiarly known in the profession, will be the foremost centre of sound medical learning in the United States.

Tenement House Reform.

The Governor of the State of New York appointed a commission last year to study the whole subject of the domiciles of the poor of New York City. The commission was composed of prominent citizens of different professions, the chairman being the editor of the famous *Century Magazine*. The commission took a large amount of evidence, which showed (as was to be expected) that the housing of the poor of this city is most discreditable. One startling discovery was made which excited unusual public interest. It was found that the large blocks of tenements which the Trinity Church Corporation owned were not supplied with water, and in other respects were deficient in ordinary sanitary appliances. A suit was brought against the corporation to compel it to correct these deficiencies. The trustees contested the suit and were defeated in the lower courts. They appealed, and within a few days the higher court has decided against them. The result has been received with great favour by the public. The commission has now reported the results of its work to the Legislature, with a Bill making sweeping changes in the building laws. The Bill is encountering much opposition from the landlords, and it is very doubtful if the really good features of the measure—such as making all tenements fireproof and supplying them with abundance of water, air, and light—will be successful.

Keely Cure enforced by Legislation.

One of the latest freaks of legislation is an effort to enforce the Keely Cure remedy in the treatment of the

¹ Journal de Clinique et Thérapeutique Infantiles, March 14th.

alcohol habit by law. The State of Massachusetts is distinguished for its conservatism in legislation, and yet its Legislature is gravely considering a Bill to compel the employment of the Keely Cure in the treatment of patients in the Massachusetts Hospital for Dipomaniacs. This ridiculous attempt to govern the methods of treatment of a disease by statutory laws in one of the oldest States of the Union creates much comment, and will probably end in total discomfiture of the advocates of this scheme for popularising an alleged "remedy" for inebriety not recognised by the medical profession.

A Statue of Dr. Gross.

Congress has passed the Bill granting permission to the American Surgical Association and the Alumni Association of the Jefferson Medical College to erect a statue to the memory of Samuel D. Gross in this city. The Bill appropriates \$1500 for a pedestal.

March 13th.

Obituary.

HAROLD J. MOLYNEUX, L.R.C.P. EDIN., M.R.C.S. ENG.

It is with sincere regret that we have to chronicle the death of Mr. H. J. Molyneux of Upholland, Lancashire, at the early age of forty-three years. He was the son of a surgeon, and studied at the Liverpool School of Medicine. Immediately on obtaining his diplomas, although only in his twenty-first year, he attended patients in his native village, and subsequently on his brother's death succeeded to the practice established by his father, which ultimately in his hands became one of the most extensive in this part of the country. About fourteen months ago he had a severe attack of hæmatemesis, from which he recovered sufficiently to resume his professional duties, but on the 2nd inst. he had a recurrence of gastric symptoms, to which he succumbed on March 9th. He was a man of great personal influence in the district, and a sound and safe practitioner; he held numerous Poor-law appointments, and was also medical officer of health to the Billinge Local Board. Of a most generous and kind disposition, he is mourned by all who knew him. The funeral took place at St. James', Orrell, on March 13th, and was attended, not only by many of his brother practitioners, but by a large gathering of the general public—a testimony of the affection and esteem in which he was held by all.

BASIL DE BEAUVOIR CAREY, M.A., M.B. CANTAB.,
M.R.C.S. ENG., L.S.A.

THE death of Dr. B. de B. Carey has brought deep sorrow on his numerous friends in Guernsey, where his promising career came to a premature close on March 17th. His health had been failing for some time, and his relatives were not unprepared for their bereavement. He was the second son of Dr. Francis Carey, who has for many years held a leading position among the medical men of the island, and, having determined to follow his father's profession, he studied at Cambridge University and St. Thomas's Hospital. He obtained the diploma of the Society of Apothecaries in 1886 and that of the Royal College of Surgeons of England in 1887. He did not, however, definitely commence practice until he had graduated as M.B. at Cambridge University in 1889, when he settled down among his friends in Guernsey, and held the appointment of surgeon to the St. Peter Port Hospital for about two years. At the time of his death he was surgeon-captain in the Guernsey Militia. Dr. Carey was a man of most amiable character and very popular among his patients, as he had been among his fellow students at both his hospital and his university. He was in his Cambridge days a very proficient and enthusiastic cricketer. He leaves a widow and one daughter.

GEORGE THOMAS LEE, M.R.C.S. ENG., L.R.C.P.

WE regret to announce the premature death of a highly promising young practitioner, who had devoted his attention to lunacy, and for whom a bright and useful future was anticipated. Mr. Lee obtained his professional education at University College Hospital, London, and later held one of the junior posts at the Leicester Infirmary. He obtained his diplomas in 1883, and at once determined to adopt lunacy as his department of practice. He soon obtained the post of assistant medical officer to Fisherton House

Asylum, Salisbury. Having held this appointment for rather more than a year, he took the similar post at the Institute for the Insane, Colon Hill, Stafford. After working here for two years it was suggested that general practice might suit him better, as—never a strong man—he was somewhat run down. However, after a very short interval, in which, upon trial, he found general practice uncongenial, he returned to his old work at Cotton-hill. In 1887, Dr. Pater of the Stafford County Asylum having died, the junior appointment was offered to Mr. Lee and accepted by him. He remained at this asylum until within a few days of his death, serving first as junior and later as senior assistant medical officer. It was during his work here that he gained the character of a conscientious and careful physician. He has left behind him many friends and many mourners.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent medical men are announced:—Dr. Victor Parisot, formerly Professor of Clinical Medicine at the Nancy Medical School.—Dr. Ljambł, formerly Professor of Clinical Therapeutics in the University of Warsaw.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—The following candidates have passed in the under-mentioned subjects:—

Surgery.—T. B. Abbott, Leeds; R. N. de Beauvais, Aberdeen; A. Harding, Royal Free Hospital; F. E. H. Keogh, St. Mary's Hospital; W. E. Kirby, University College; P. Kitchen, Leeds and St. Mary's Hospital; A. E. Philipps, Guy's Hospital; J. A. K. Renshaw, Cambridge University and Manchester; J. Spears, London Hospital; G. E. Williams, London Hospital.
Medicine, Forensic Medicine, and Midwifery.—G. W. Brown, St. Thomas's Hospital; W. J. Gillespie, St. Bartholomew's Hospital; A. Harding, Royal Free Hospital; P. Kitchen, Leeds and St. Mary's Hospital; R. W. Middleton, Leeds; H. S. Oliver, Charing-cross Hospital; A. E. Philipps, Guy's Hospital; E. P. Staples, St. Mary's Hospital.
Medicine and Forensic Medicine.—T. H. Wilkins, Charing-cross Hospital.
Medicine.—S. H. L. Archer, London Hospital; R. G. Jones, London Hospital.
Forensic Medicine and Midwifery.—J. S. A. Murphy, Leeds; G. A. Skinner, Guy's Hospital.
Forensic Medicine.—G. C. Jackson, Cambridge University and St. Mary's Hospital; A. L. M. Churchill, Westminster Hospital.
Midwifery.—G. Downes, Dublin; T. B. Abbott, Leeds.
To Messrs. Archer, Churchill, Gillespie, Harding, Kitchen, Middleton, Philipps, Skinner, Spears, Staples, and Williams was granted the diploma of the Society.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 14th, the President, Mr. Makeig Jones, being in the chair. Dr. Ernest Knight related a fatal case of jaundice in a boy six years of age. The first attack of jaundice was slight and transient. A month later he came under observation again with very deep jaundice and a much engorged liver. In a fortnight toxic symptoms set in, and two or three days after this the liver began to diminish in size. The patient died four weeks from the second onset of jaundice. At the post-mortem examination, which was limited to the abdomen, a mass of tuberculous glands was found in the portal fissure, compressing the hepatic duct. There was no sign of tuberculosis elsewhere in the abdomen. Mr. Makeig Jones showed a man forty-seven years of age the subject of mixed melanoderma and leucoderma. Except for the colouration the skin appeared perfectly normal. The hairs on the white patches in the axilla were also white. After an obscure illness three years ago he noticed that his face, trunk, and arms became bronzed, and then white spots appeared which gradually enlarged into big patches. Dr. Alfred Robinson showed a man with progressive muscular atrophy. Dr. Burges showed a specimen of malignant stricture of the cardiac end of the œsophagus. Vomiting sometimes as long as an hour after taking food was complained of, but throughout the illness the patient was never aware of any difficulty of swallowing. Dr. Hunt related a case of Exophthalmic Goitre with marked brownings of the skin. Reference was made to a similar case recorded by Carrington in the Transactions of the Ophthalmic Society for 1886.—Mr. Richard Favell reported a case of puerperal eclampsia, and made remarks on the treatment of this affection.—The President, Dr. Keeling, Dr. Martin, Mr. Dale James, Dr. Arthur Hall, and Dr. Burges took part in the discussions.

THE ROYAL COMMISSION ON TUBERCULOSIS.—Mr. Shaw-Lefevre had a private interview at the House of Commons with the National Federation of Butchers and others on Tuesday night last with reference to the report of the Commission. Mr. Field, M.P., introduced the deputation, and urged the importance of having the report of the Commission issued at once. Mr. Shaw-Lefevre said that he was anxious to have the report published, but the delay had arisen from the death of Lord Basing. The secretary of the Commission reported that the greater portion was in type.

BIRMINGHAM GENERAL HOSPITAL.—The annual meeting of the governors of this hospital was held on March 20th. Mr. William Kenrick, M.P., who presided, said that it was the 115th annual report which was before the meeting, and that the progress made during a century would appear from the fact that the building was at the time of its erection "outside the village of Birmingham, being generally described as near Sutton Coldfield." The original number of beds was only 37; at present there are 270, and the premises now in course of construction will accommodate 340 patients. During 1894 there were 4336 in-patients and 49,835 out-patients, the average length of residence of the in-patients being twenty-four days; at the Jaffray Branch Hospital 237 patients were admitted.

THE CHEMICAL SOCIETY.—The annual meeting of this society was held in Burlington House on Wednesday afternoon last, Professor Armstrong presiding. The Faraday Medal was bestowed by the council upon Lord Rayleigh in recognition of his services to physics generally and of the discovery of argon. Lord Rayleigh, in returning thanks for the honour that had been done him, made a graceful allusion to the prominent share in the discovery enjoyed by Professor Ramsay. Professor Ramsay contributed the sensation of the meeting by announcing the discovery of helium, a discovery upon which we comment in another column. The annual dinner of the society was held on the same evening in the Whitehall Rooms of the Hotel Métropole, when the company had the pleasure of listening to a brilliant speech from Mr. A. J. Balfour.

UNIVERSITY COLLEGE HOSPITAL.—The annual meeting of the governors of this hospital was held in the board-room on March 22nd, Mr. Henry Lucas presiding. During 1894 there were 3035 in-patients, the average daily number resident being 181, and the average duration of stay being 21½ days. The expenditure had exceeded the income by about £1000, and funds are urgently needed. Last year's festival dinner resulted in contributions amounting to about £4850, and the award of the Hospital Sunday Fund was £1288. Mrs. Nathaniel Montefiore had endowed a bed by a donation of £2000, and friends of the late Professor Marcus Beck, surgeon to the hospital, had partially endowed another. The arrangements for the rebuilding of the hospital were progressing satisfactorily, and the efforts of the medical and surgical staff had been successful in raising about £3000 for the building fund.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—A meeting of the Scottish Division of this association was held in the Hall of the Faculty of Physicians and Surgeons, Glasgow, on March 14th. After the preliminary business had been transacted a resolution expressing the sense of the great loss which the association has sustained in the death of Dr. Hack Tuke was submitted by Dr. Ireland and unanimously adopted. Dr. G. M. Robertson read a paper, "Sane or Insane?", which was followed by considerable discussion; and Dr. Turnbull showed the plans of an addition, in the shape of a "hospital block," which has recently been made to the Fife and Kinross District Asylum. A meeting of the South-Western Division of the association will be held at the City Asylum, Fishponds, Bristol, on Thursday next, April 4th, at 2.30 P.M. The City Asylum is half-an-hour's drive from Bristol and one mile from Fishponds Station. Dr. H. Bristowe will contribute a further note on the Relationship between General Paralysis and Chronic Renal Disease. Dr. J. V. Blackford will read notes on a case of Ataxic Insanity. Dr. Law Wade will move the following resolution and initiate a discussion thereon: "That it is desirable that power be given to the visiting committees of asylums and hospitals for the insane to grant gratuities to the widows or orphans of officials who may die after long service or be fatally injured in the discharge of their duties."

THE HOSPITALS FOOTBALL CHALLENGE CUPS.—On Monday last the final ties were played in these challenge competitions under both rules. St. Bartholomew's competed with Guy's under the Association code, and came off victorious by one goal to nothing. St. Thomas's met St. George's in the final tie under Rugby Union rules and secured a substantial victory by three goals and three tries to nothing.

The one hundred and fifty-ninth annual meeting of the governors of the Bristol Royal Infirmary was held on Tuesday last. The report showed that 1000 more patients had been treated in 1894 than in 1893, whilst the cost per bed had sensibly decreased. The resignation of Dr. Shekleton of the secretaryship to the institution, on the ground of failing health, was accepted with the greatest regret by the meeting, the words of commendation which Mr. C. D. Cave, the president of the hospital, bestowed upon Dr. Shekleton's work being received with general applause.

HOSPITAL SATURDAY FUND.—The annual meeting of this fund was held at the Mansion House on the 23rd inst. Mr. Reginald B. D. Acland, who, in the absence of the Lord Mayor, presided, stated that £17,609 had been distributed among London medical charities during the past year. The street collection had again fallen off, but the workshop collection showed an increase, the former amounting to only £4820, while the latter had reached the sum of £14,514, nearly the whole of which was contributed in pennies. On the motion of Canon Scott Holland a resolution approving of the principle of soliciting weekly subscriptions from working men was agreed to. The street collection for 1895 was fixed for July 13th. For our part we should be glad to know that the street collection was to be abandoned. It is not pleasant to see ladies touting for money in the streets, even in the divine cause of charity, and it affords an example of which other less worthy institutions are too apt to take advantage. The "man in the street" is notoriously wanting in discrimination in such matters.

BRITISH ORTHOPÆDIC SOCIETY.—A meeting of this society was held on Jan. 31st. There were about twenty members present. Mr. Ewens of Bristol was voted into the chair and made a few introductory remarks. Mr. Muirhead Little then showed a case of inveterate Talipes Equino-varus in both feet successfully treated by removal of wedges of bone from the astragalus and os calcis. Messrs. Keetley, Reeves, Noble Smith, Brodhurst, Walsham, Freer, and Ewens discussed the case and Mr. Little replied. Mr. Tabby presented a case of Contracted Elbow, Wrist, and Fingers due to pressure on the median nerve by scar tissue. The nerve was freed by operation and the flexor tendons of the wrist were subsequently divided, with complete restoration of the functions of the hand. Messrs. Keetley, D'Arcy Power, Reeves, and Walsham discussed the case and Mr. Tabby replied. Mr. Luke Freer brought forward a specimen, the amputated left leg of a case of congenital Talipes Varus due to deficiency of the left tibia. A paper was read by Mr. Keetley on the Causes of Rotation in Scoliosis. An animated discussion followed. The society adjourned after arranging for the next meeting at Liverpool in May.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Shops' Early Closing Bill.

THE Select Committee appointed by the House of Commons to inquire into the subject of this Bill is now engaged examining witnesses. Apart from the adjustment of details the only point at issue seems to be whether further trial should be given to voluntary effort in the matter of early closing, or whether the time has now arrived for the interference of the Legislature. So far the evidence taken tends to the latter conclusion and is consequently in favour of the Bill.

Accommodation for the Insane in Dublin.

In the House of Lords on Monday, March 25th, a question was put to the Government with reference to the Richmond Asylum in Dublin, and Lord Ribblesdale, in the course of his reply, said that the Chief Public Health Officer of Dublin recently reported favourably on the healthiness of the site of the Asylum. He found that some limited portions of the soil had been contaminated by sewage in the vicinity of old drains, but that he considered could be remedied. The inspectors of lunatics had advised that, with certain alterations which were about

to be made, the Richmond Asylum could be continued with advantage as an institution for the care and treatment of the insane poor of the City of Dublin. The Resident Medical Superintendent had stated that in his opinion the site was not a suitable one for an asylum. Much had, however, been done to improve it by the execution of a complete system of drainage and the purchase of some additional land and alterations, and additions were now in contemplation for the improvement of the buildings.

Reformatory and Industrial Schools.

The Government have introduced into the House of Commons a Bill for enabling children to be sent from the Channel Islands to reformatory or industrial schools in Great Britain. In this connexion it may be added that the Government intend to appoint a committee to inquire into the whole question of the management of reformatory and industrial schools.

Imbecile and Epileptic Children in Workhouses.

Early in February a motion was made by Sir Walter Foster for a return showing the number on Sept. 1st, 1894, of imbecile and epileptic children under sixteen years of age in each workhouse, separate infirmary, school, or other similar establishment belonging to the guardians of unions in England and Wales (excluding the metropolis), distinguishing the number of such children who were of dirty habits and the number who would, in the opinion of the medical officer, be likely to be improved by special training. This return has been prepared and is now before Parliament. It is prefaced with a summary note which explains that there are 618 extra-metropolitan unions in England and Wales, that the particulars in the return are drawn from 175 unions, and that the remainder of the unions have no such children in their workhouses. The number of children who were imbecile only was 294 (male 174, female 120), the number epileptic only was 93 (male 55, female 38), and the number both imbecile and epileptic was 98 (male 52, female 46): total, 485 (male 281, female 204). The number of these children of dirty habits was 223 (male 142, female 81), and the number who, in the opinion of the medical officer, would be likely to be improved by special training was 178 (male 95, female 83).

HOUSE OF COMMONS.

THURSDAY, MARCH 21st.

Potato Disease.

Mr. John Morley, answering a question put by Mr. W. Johnston, said that field experiments for testing the value of applications of copper sulphate and lime to the potato plant as a preventive of potato disease were carried out by the Agricultural Department of the Irish Land Commission in 1891, 1892, and 1893. The results obtained from the experiments conducted in 1892 and 1893 proved conclusively that a proper application of the mixture used was of great value as a preventive. It was not therefore considered necessary to continue the field experiments in 1894, but field demonstrations were given in a small district of the counties of Derry and Antrim, the same mixture being used.

The Accommodation for Members.

Mr. Cremer asked the First Commissioner of Works whether, in view of the evidence laid before the Committee on the Accommodation of the House of Commons during last session, he would endeavour to make arrangements for increasing the accommodation for members.—Mr. Herbert Gladstone replied that he was afraid he could not give this undertaking.—Mr. Cremer then asked whether he would consider a proposal to reappoint the Committee, and to this Mr. Gladstone replied that no practical advantage would come from the reappointment of the Committee.

FRIDAY, MARCH 22nd.

The Vaccination Commission.

Mr. Hopwood asked the Parliamentary Secretary to the Local Government Board why neither Sir George Buchanan nor Dr. Ballard, formerly chief medical officer and medical inspector of the Local Government Board, offered themselves for examination in defence of vaccination before the Royal Commission, whether both suffered from indisposition when their attendance was required, and whether, seeing that Sir George Buchanan had since recovered sufficiently to undertake the chairmanship of the Royal Commission on Tuberculosis, there was any obstacle present to prevent either of those gentlemen from being examined if the Royal Commission on Vaccination desired it.—Sir Walter Foster replied that it was not the practice of officers of the Local Government Board to offer themselves for examination before a Royal Commission. Some inquiry was made as to the attendance of Sir George Buchanan and Dr. Ballard before the Royal Commission on Vaccination, and it was the fact that both these gentlemen were then prevented by indisposition from attending. He regretted to state that Sir George Buchanan was still out of health, and on this account he undertook the chairmanship of the Royal Commission on Tuberculosis with great reluctance.

MONDAY, MARCH 25th.

Pleuro-Pneumonia.

In answer to a question Mr. Herbert Gardner, President of the Board of Agriculture, said that a veterinary inspector had no power to order slaughter either in pleuro-pneumonia or glanders. In pleuro-pneumonia the power to slaughter rested absolutely with the Board of Agriculture, the compensation paid where the animal was not diseased being its value immediately before it was slaughtered. In glanders the power to slaughter rested with the local authority.

Substitutes for Butter.

Mr. W. C'Brien asked the Chief Secretary to the Lord-Lieutenant of Ireland whether he had yet come to any conclusion as to the introduction of a Bill this session for remedying the defects of the existing law in respect of fraudulent substitutes for butter. Mr. John Morley in reply said he was well aware of the importance of this matter, but,

at the present moment there was a committee at work with regard to it, and immediately upon the receipt of the committee's report the question of amending legislation would be carefully considered.

Female Factory Inspectors.

Mr. Asquith, replying to a question on this subject by Mr. Sexton, said there were now four female inspectors of factories. They were not assigned to any particular locality, but travelled to every part of the United Kingdom where their services were required. Notices were exhibited in all factories and workshops in Ireland where women were employed stating that complaints might be sent to the female inspectors, and all such complaints were promptly inquired into by one of the female inspectors. With the staff and resources which were at present at his disposal he thought that the female inspectors were more usefully employed in peripatetic visits than if they were stationed in particular districts.

TUESDAY, MARCH 26th.

The New Factory Legislation.

Mr. Asquith answered a question put by Mr. Woods with reference to woolsorters and the Bill of the Government amending and extending the Factory and Workshops Act. He said that an amendment would be proposed by the Government when the Bill was in committee to extend to their workshops the power given to the Secretary of State by Section 8 of the Act of 1891 to make special rules for industries certified to be dangerous or injurious. An inquiry, he added, had for some time been in process by the Factory Department into certain industries which involve the risk of injury to the persons employed, among them being wool-sorting, where there was a possibility that anthrax might be contracted, and this inquiry was nearly completed. On its completion the question where special rules were desirable for the occupation of wool-sorting would be considered.

WEDNESDAY, MARCH 27th.

Better Houses for Farm Servants in Scotland.

The House engaged in a debate of some length on the motion made by Mr. Seymour Keay for the second reading of a Bill to provide for the better housing of farm servants in Scotland. The special object of the Bill, as Mr. Seymour Keay explained, is to strike at abuses in connexion with what is known in Scotland as the "bothy system." It provides that every building on a farm used as a dwelling or sleeping place for farm servants shall be provided with sufficient and suitable accommodation in the way of cubic contents, fireplaces, sanitary arrangements, and fixtures, having regard to the number of inmates. It also provides that when persons of both sexes inhabit the same "bothy" there shall be proper separate accommodation for each sex. Power is given to the local authority to make and enforce by-laws and, when its medical officer of health reports that the provisions of the Act are not complied with, to order the landlord of the premises to make such alterations and additions as may be required to give sufficient suitable and proper accommodation. Objection was taken to the Bill on the ground of its limited application, one member describing it as "a scrap of piecemeal legislation." Dr. Farquharson strongly supported the Bill and predicted that the local authorities in Scotland would carry out its provisions with prudence and discretion. In the end the Bill was read a second time.

IN COMMITTEE.

Food Products Adulteration.

A Defence of Margarine.

The Select Committee of the House of Commons on this subject resumed its inquiry on Tuesday, March 26th, Sir Walter Foster presiding.

Mr. Hickey, a wholesale butter merchant in Manchester and a representative of the Chamber of Commerce of that city, gave evidence in great detail as to the presence of water in butter. The trade in Manchester, he said, had given this matter the most careful attention and taken great pains to acquire information with regard to it, and had come to the conclusion that any standard under 20 per cent. would be unfair to the producer of Irish salt butter. The result of overworking butter in order to get the water out of it was to make it altogether unsalable. An analysis of 350 samples of Irish salt butter taken in 1893 showed that 80 per cent. of them contained above 15 per cent. of moisture. If they established a 15 per cent. standard they would shut out 35 per cent. of Danish butter, 22 per cent. of English butter, and 50 or 60 per cent. of Irish salt butter. This Irish salt butter was scarcely sold in London, the great markets for it being Lancashire, Yorkshire, and Wales. As to margarine, the witness said he would prohibit colouring, because the object of colouring was to facilitate fraud. He admitted that according to the present law a man mixing 50 per cent. of butter with margarine must call it margarine, which it was not. It was only because mixtures conduced to fraud that he would prohibit them. He did not think that any method of labeling would be a sufficient protection against fraud. The great grievance the trade had was that the present law was not stringently administered—that, in fact, it had hopelessly broken down.

Mr. J. J. Thompson, another Manchester butter merchant, examined by the Chairman, said he imported margarine, most of it coming from Holland, and all of it being marked "margarine." He considered margarine and mixtures of margarine and butter most useful as articles of food. They were quite wholesome, and there was little difference between them and butter in the matter of nutrition. He could quote no scientific authority in support of this—it was merely his own opinion. He regarded margarine as quite as legitimate an article of commerce as butter, and to interfere with its sale would be wrong and very injurious. He did not think the working classes were defrauded, because they bought margarine for its value, which was lower than the price of butter. It was true that margarine came into competition with the cheap butters now sent from the colonies; that might be injurious to the butter makers, but not to the public. Whether he preferred a pound of New Zealand butter to a pound of margarine mixture would depend on the quality of the former, because it often went stale and was very inferior to the latter. In Lancashire margarine would sell in preference to all except the very finest quality of Australian butter. Q. Margarine is largely sold, is it not, to public institutions?—A. Yes; but always under the name of margarine. Q. And supplied to the inmates as butter?—A. Yes, that is so. Margarine was packed in shapes and sizes in accordance with the desire of the

customer and to suit the requirements of the district. He did not think that any interference with the shapes or makes of margarine mixtures would tend to diminish fraud upon the public, but he was sure that if the present law were properly enforced it would prevent fraud. He would not object to travelling inspectors going about to see that the Act was carried out and that local authorities did their duty. He did not know of any adulterated butter coming into the country now. People were afraid now because of the action taken here and in foreign countries. In his opinion all the butter now received in this country was pure butter and contained no percentage whatsoever of margarine. He made this statement in spite of the assertion that Brittany butter was sold cheaper here than in the country where it was made. Prosecutions, in his opinion, should be taken under the Margarine Act and not under the Sale of Food and Drugs Act. To license dealers in margarine would do no good because almost every retailer sold margarine nowadays. The public knew this, and a licence would tell them no more. There could not be a doubt that the introduction of these cheap Colonial butters had reduced the price of margarine very much.

By Sir Charles Cameron: One advantage possessed by margarine was that it contained much less water than butter. For instance, he had never heard of margarine that contained 15 per cent. of water, although this seemed to be common in the case of butter. He would not interfere with the colouring of margarine any more than of butter, and he thought that it would be an injustice to the working classes to say that they must take their margarine white. Another thing he wished was that butter mixtures should be permitted to be sold as such, and not branded "margarine."

By Mr. Whiteley: The people of Lancashire were very shrewd, and knew perfectly well that if they went into a shop and asked for butter at 6d. or 8d. per pound, they could not get genuine English fresh butter, no matter how the retailer might describe the article he offered. Some New Zealand butter could be sold at 6d. per pound, and he had no hesitation in saying that margarine at the same price would be found infinitely superior to it.

The Committee then adjourned.

The Committee met again on Wednesday, March 27th, with Sir Walter Foster in the chair.

Mr. James Hudson, engaged in the butter and provision trade in London, and a member of the London Chamber of Commerce, said he was not opposed to the sale of margarine as such, but he objected to the mixing of margarine and butter, because it was the cause of all the fraud and did a great deal of injury to butter makers in this country. Very large quantities of butter were coming here from our colonies at a very small price, and he believed that this new trade would interfere for a time at least with the sale of margarine. The colonial butter did not contain so much water as Irish butter and up to the present had proved good and sound and free from any trace of margarine. The large profits made by makers and retailers of spurious butter rendered them indifferent to the fines imposed on conviction. He would therefore increase the fines and send offenders to gaol on the third and subsequent convictions. Great quantities of margarine were sold in all the towns of Scotland, but especially in Edinburgh and Glasgow. He could only account for this by the Scotch people not caring to pay 1s. per lb. for butter when they could get margarine at half that price, which satisfied them. He should say that the margarine sold in Scotland contained no more butter than what came from the milk used in the process of manufacture. He recommended that butter and margarine should not be sold in the same shop, that all dealers in the latter should be licensed, and that they should be compelled to sell it in a particular shape and with a particular package. He was in favour of having margarine coloured, because in its natural colour it would look nasty and would be unsaleable. He also recommended the appointment of travelling inspectors. He had no hesitation in saying that many of the inspectors under the present Act were "squared." Cases were known where inspectors went into a shop and, on asking for a pound of margarine, were either supplied with fresh butter, which had cost, perhaps, 1s. 4d., or had found half a sovereign in the scales. He favoured the prohibition of mixtures, thinking that margarine was quite good enough to be sold upon its merits.

Mr. Harold Faber, Commissioner for the Agricultural Department of the Danish Government, said his duties in this country were to look after the interests of the agricultural products of Denmark. From time to time he received information from different parts of the country as to the sale of other butter and butter substitutes under the name of Danish butter, and he made inquiry into the circumstances of each case. He also kept under his observation improvements effected in this country and elsewhere in the making of butter and other farm products. The law of Denmark required that margarine should always be kept in certain shaped packages marked in a certain way. This provision was found most effective for its purpose of preventing imposition. They had inspectors appointed with no other duty than to look after the administration of the Margarine Acts, who inspected butter and margarine where they were manufactured, or kept for sale, or stored. All the expense was borne by the Central Government, not by the local authorities. They put a limit upon mixtures. By Act it was prohibited to add more than 50 per cent. of butter fat, but on account of the colour section of the Act it was impossible to have as much butter as 50 per cent. in the mixture. This section provided that the colour of margarine must not exceed a certain yellow tint, and if more than 20 per cent., or even 20 per cent., of butter was added the mixture would exceed in colour that pale tint. Therefore, as matter of practice, they never had more than say 25 per cent. of butter in the mixtures. It might be that certain conditions of weather baffled the colour test, but there were other tests that could be applied. The witness showed to the Committee a number of colour-plates used for this test. He admitted that it was a delicate and difficult test, but in Denmark, he said, the margarine inspectors performed it so well that they were agreed among themselves and produced excellent results with it. The penalties in Denmark for the minor offences ranged from £2 10s. to £10, while for the more serious offences imprisonment was awarded. From the experience of Denmark and what he had seen in this country he had no hesitation in saying that even high fines were not sufficient to put down fraud altogether. His view with regard to mixtures was that they should be prohibited by law, because they gave rise to unfair competition and swindling. He also thought that in this country, as in Denmark, margarine should be sold in a particular shape and with a particular mark upon it.

The Committee then adjourned for a week.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

ALEXANDER, S. R., M.D. Lond., M.R.C.S., has been appointed Medical Officer for the First Sanitary District of the Faversham Union.
BROOKS, CHAS., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Gerrard's Cross Sanitary District of the Eton Union.
BROWNE, EDWARD, M.A., M.R.C.S., L.R.C.P., has been appointed House Surgeon to the West London Hospital, Hammersmith, W.
COLWELL, J. K., has been appointed Public Analyst by the Clerkenwell Vestry.
CUTFIELD, A. B.Sc. Lond., M.R.C.S., has been appointed Medical Officer for the Man of Ross Lodge of Oddfellows, Manchester Unity, vice Knapp, resigned.
DRAGE, LOVELL, M.D. Oxon., B.Ch., M.R.C.S., has been reappointed Medical Officer of Health for the Hatfield Rural Sanitary District.
FLAVIN, F. J., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Seventh Sanitary District of the Ashton-under-Lyne Union, vice Kishys.
GAULT, EDWARD LESLIE, M.A., M.B., B.S. Melb., has been appointed Ophthalmic Surgeon to the Alfred Hospital, Melbourne.
HARSTON, L. DE C. B., L.R.C.P., L.M. Edin., M.R.C.S., has been appointed Medical Officer for the Pirbright Sanitary District of the Guildford Union, vice Brown, resigned.
INGLIS, A. M., M.D. Edin., L.R.C.S. Edin., M.R.C.S., has been appointed Consulting Physician to the Cheltenham General Hospital.
LORIMER, J. A., L.R.C.P. Lond., M.R.C.S., has been reappointed Medical Officer of Health for the Farnham Rural Sanitary District.
MITCHELL, R., M.D., M.Ch. Irel., has been appointed Medical Officer for the Hooton Pagnell Sanitary District of the Doncaster Union.
MURDOCH, MARY C., L.R.C.P., L.R.C.S. Ed., L.F.P.S. G., has been appointed Assistant Medical Officer to the North-Eastern Fever Hospital, Tottenham.
PAGET, OWEN T., M.B., B.C. Cantab., has been appointed Resident Medical Officer to the St. George's and St. James's Dispensary, W.
PALMER, EDWIN C., M.B., B.C. Camb., L.R.C.P. Lond., M.R.C.S., has been appointed Surgeon to the Lincoln General Dispensary, vice Dalton, resigned.
RUSSELL, W. A. G., M.B., C.M. Aberd., has been appointed Medical Officer for the Wingage Sanitary District of the Kington Union.
SHAW, CECIL EDWARD, M.A., M.D., M.Ch. R.U.I., has been appointed Assistant Surgeon to the Belfast Ophthalmic Hospital.
STILL, GEO. F., M.A., M.B. Cantab., has been appointed Medical Registrar and Pathologist to the Hospital for Sick Children, Great Ormond-street, Bloomsbury, London.
STUCKLING, C. W., M.D. Lond., M.R.C.P., M.R.C.S., has been reappointed Consulting Physician to the Hockley Provident Dispensary.
TAIT, LAWSON, M.D. N.Y., F.R.C.S. Edin., F.R.C.S. Eng., has been appointed Consulting Surgeon to the Hockley Provident Dispensary.
TAYNTON, W., L.R.C.P. Edin., M.R.C.S., has been appointed Medical Officer for the Linton Sanitary District and the Workhouse of the Linton Union.
WEISER, W. W., L.R.C.P. Edin., M.R.C.S., has been appointed Medical Officer of Health for the Crewkerne Urban Sanitary District.

Vacancies.

For further information regarding each vacancy references should be made to the advertisement (see Index).

BLOOMSBURY DISPENSARY.—Physician. An honorarium of £105 is annually voted to the physician. Applications to Mr. C. E. Baker, 12, Bloomsbury-street, W.C.
COUNTY ASYLUM, Dorchester.—Second Assistant Medical Officer, unmarried. Salary to commence at £130, rising £10 annually to £160.
COUNTY ASYLUM, Rainhill, near Liverpool.—Assistant Medical Officer, unmarried. Salary to commence at £100 a year, with prospect of an annual rise of £25 up to £200, and further increase according to promotion, together with furnished apartments, board, attendance, and washing.
EAST LONDON HOSPITAL FOR CHILDREN, Glamis-road, Shadwell, E.—House Physician. Board, lodging, &c. provided.

HOLBORN UNION.—Medical Officer for the Union Schools at Mitcham, Surrey. Salary £100 per annum, non-resident. Applications to the Clerk to the Guardians, Holborn Guardians' Office, Clerkenwell-road, E.C.

HOLLOWAY AND NORTH ISLINGTON DISPENSARY.—Two Honorary Medical Officers for the Rupert-road Branch of the Institution. Applications to the Hon. Secretary, 68, Aldermanbury, E.C.

LEICESTERSHIRE AND RUTLAND ASYLUM.—Assistant Medical Officer, unmarried. Salary £150, increasing £10 yearly to £200, with board, lodging, and washing. Applications to the Clerk to the Visitors, 10, New-street, Leicester.

LINCOLN COUNTY HOSPITAL, Lincoln.—House Surgeon, unmarried. Salary £100 per annum, with board, lodging, and washing.

LONDON COUNTY ASYLUM, Hanwell, W.—Fifth Assistant Medical Officer. Salary £120 per annum, rising by £5 a year to £150, with board, furnished apartments, and washing. Applications to Clerk of the Asylums Committee Office, 21, Whitehall-place, S.W.

MILLER HOSPITAL AND ROYAL KENT DISPENSARY, Greenwich-road, S.E.—Junior Resident Medical Officer, for six months. Salary at the rate of £30 per annum, with board, attendance, and washing.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART AND PARALYSIS, 32, Solihol-square, London. Clinical Assistants for the Electrical Department.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, Shoreditch, N.E.—Physician. Applications to the Secretary, Office, 27, Clement's-lane, E.C.

NORTHUMBERLAND COUNTY ASYLUM, Morpeth.—Clinical Assistant. Board and residence provided.

NOTTINGHAM GENERAL DISPENSARY.—Junior Assistant Resident Surgeon, for six months. Salary at the rate of £120 per annum, with rooms, fire, and light.

ROYAL HOSPITAL FOR SICK CHILDREN, Glasgow.—House Surgeon. Salary £60, with board and washing. Also Assistant House Surgeon. Salary £30, with board and washing.

WEST RIDING ASYLUM, Menston, near Leeds.—Third Assistant Medical Officer. Salary to commence at £130 a year, rising £10 annually to £160, with board and apartments.

Births, Marriages, and Deaths.

BIRTHS.

ADAMI.—On March 24th, at Durocher-street, Montreal, Canada, the wife of J. George Adami, M.A., M.D. Cantab., of a daughter.
BALL.—On March 26th, at Upper Winpole-street, the wife of Dr. J. B. Ball, of a daughter.
COLLINS.—On March 23rd, at Waveney-mansions, Fairhazel-gardens, South Hampstead, the wife of E. Treacher Collins, F.R.C.S., of a daughter.
COWEN.—On March 23rd, at Walpole Lodge, New Malden, Surrey, the wife of George Cowen, M.D., of a daughter.
CUTCLIFFE.—On March 20th, at North Tawton, North Devon, the wife of Montagu Cutcliffe, L.R.C.P. Lond., M.R.C.S., of a daughter.
DIXEY.—On March 18th, at Oxford, the wife of Frederick A. Dixey, M.D., Fellow of Wadham College, of a son.
LANCASTER.—On March 8th, at Rockdale, Clitheroe, the wife of Lewis T. Lancaster, M.B. Edin., of a daughter.
MACKAY.—On March 16th, at The Cloisters, Knaresboro', the wife of Ian D. Mackay, B.A., M.B., of a daughter.
MORTON.—On March 21st, at Church-green-east, Redditch, the wife of Edwin Morton, M.D., of a son.
RAMSAY.—On March 24th, at Jesmond Dene, Bournemouth, the wife of F. Winsome Ramsay, M.S., F.R.C.S. E., of a son.

MARRIAGES.

CARTER—JUST.—On March 26th, at Westbury-on-Trym, by the Rev. S. Baker-Penoyre, Thomas Moravian Carter, M.R.C.S., L.R.C.P., to Adelheid Clara, youngest daughter of H. W. Just, Esq., Bristol.
SANDIFER—LEE.—On March 20th, at St. Augustine's Church, Highbury, Henry Stephen Sandifer, M.D., F.R.C.S., son of the late Jabez Sandifer, Esq., of Highbury-hill, to Evelyn, youngest daughter of Henry Lee, Esq., J.P., of Earlham, Highbury-quadrant.

DEATHS.

CAREY.—On March 17th, at Hirzel House, Guernsey, Basil de Beauvois Carey, M.A., M.B. Camb., aged 32.
CHATER.—On Feb. 14th, at Hannans, Western Australia, Arthur Reginald Chater, M.R.C.S., aged 28.
HILLIER.—On March 22nd, at Beccles, Susan Hillier, widow of the late Thomas Hillier, M.D. Lond., F.R.C.P., Physician to the Hospital for Sick Children and to University College Hospital, London, of cardiac syncope in her sleep, aged 66.
JESSETT.—On March 23rd, at Clenthorpe, The Avenue, Surbiton, the residence of his sister, George Thomas Lee, M.R.C.S., L.S.A., son of Fred. Bowreman Jessett, F.R.C.S., aged 34. For eight years senior assistant medical officer of the Stafford County Lunatic Asylum.
LEIDS.—On March 9th, suddenly, at the Europa Hotel, Gibraltar, Thomas Leeds, M.R.C.S. Eng., aged 55.
SMITH.—On March 20th, at 111, Blackfriars-road, S.E., Walter Stephen Smith, L.S.A., aged 67 years, late of Sheffield.
STRUTHERS.—At Hill End, New South Wales, on Feb. 17th, James Struthers, M.D., aged 35 years, second son of Emeritus-Professor Struthers, M.D., 24, Buckingham-terrace, Edinburgh.
TOWERS-SMITH.—On March 16th, at Harley-street, Cavendish-square, W., Towers-Smith, M.R.C.S., aged 59.
WICKHAM.—On March 13th, at Polmont, N.B., Walter Wickham, M.R.C.S., Barrister-at-law, aged 38.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (1 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynecological, by Physicians. 2 P.M.), Soho-square (2 P.M.), Royal Orthopaedic (2 P.M.), City Orthopaedic (4 P.M.).

TUESDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1.30 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Gt. Northern Central (2.30 P.M.).

WEDNESDAY.—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), National Orthopaedic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.).

THURSDAY.—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (2 P.M.), Soho-square (2 P.M.), North West London (2 P.M.).

FRIDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.).

SATURDAY.—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY.—ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (40, Leicester-sq., W.C.).—8 P.M. Mr. G. G. Campion: Studies in Superior Protrusion (illustrated with lantern slides). Mr. G. Brunton: (1) A Hodge Right-angle Handpiece altered to adapt it for use in Close Bites and Difficult Positions; (2) A new Amalgam Balance made in one piece.

TUESDAY.—PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Voelcker: Carcinoma of Ureter.—Dr. F. Hawkins: Congenital Obliteration of Bile-duct.—Mr. Jackson Clarke: Sarcoma Mammary.—Mr. E. Willett: Carcinoma of Bed of Thumb-nail.—Mr. L. A. Bidwell: Carcinoma of Stomach treated by Gastro-duodenostomy.—Dr. Lee Dickinson: Duodenal Ulcers in Women.—Dr. P. Weber: Cirrhosis of Liver in Child. Card Specimens.—Dr. A. A. Kanthack: (1) (with Mr. C. B. Lockwood) Psammoma of Tunica Vaginalis; (2) Psammoma (?) of Mesentery; (3) Psammoma of Vermiform Appendix and Ovary; (4) (with Mr. E. L. Lloyd) Metaplasia of Omental Epithelium into Squamous Epithelium; (5) (with Dr. C. P. White) Giant Cells in Innocent and Malignant Tumours of Epithelial Origin.—Dr. Voelcker: Ulceration of Gall-bladder in Typhoid Fever.—Mr. H. Snow: Malignant Reversion of Mammary Cystic Fibromata.—Dr. Lee Dickinson: Solitary Kidney with Two Ureters.

WEDNESDAY.—OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Dr. Cullingworth and Dr. Duncan. Adjourned Discussion on Dr. Probyn-Williams and Mr. Lennard Cutler's paper on "Some Observations on the Temperature Pulse, and Respiration during Labour and the Lying-in." Dr. Remfrey: List of Ovariectomies in Women over Eighty; A case aged Eighty-three complicated by Epithelioma of the Vulva.

THURSDAY.—HARVEIAN SOCIETY.—8.30 P.M. Mr. Howard Marsh: A Clinical Study of the more important forms of Abscess.

FRIDAY.—WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—8 P.M., Special General Meeting. 8.30 P.M., Ordinary Meeting. Papers:—Dr. Coutts: Treatment of Empyema in Children.—Mr. S. Paget: Three cases of Secondary Malignant Disease of Pleura. Card Specimens.—Dr. Parkes Weber: Ruptured Heart.—Mr. Lake: Nasopharyngeal Polypus and Large Nasal Spur.—Mr. S. Paget: Ruptured Spleen.

WEST KENT MEDICO-CHIRURGICAL SOCIETY (Miller Hospital, Greenwich).—8.15 P.M. Discussion on Antiseptics. The Discussion will be opened as follows:—Antiseptics in General Surgery by Mr. John Poland; in Midwifery and Gynaecology by Dr. Horrocks; in Medicine by Dr. Newton Pitt; in Ear and Throat Surgery by Dr. Bzard; in Eye Surgery by Dr. Ernest Clarke.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY.—ROYAL COLLEGE OF SURGEONS.—5 P.M. Mr. J. H. Targett: Recent Additions to the Museum of the College.

ROYAL INSTITUTION.—5 P.M. General Monthly Meeting.

SOCIETY OF ARTS.—8 P.M. Dr. D. Morris: Commercial Fibres.

TUESDAY.—ROYAL INSTITUTION.—3 P.M. Prof. Charles Stewart: The Internal Framework of Plants and Animals (XII).

THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—3 P.M. Subject of Lecture: Earth.

ROYAL COLLEGE OF PHYSICIANS, LONDON.—5 P.M. Dr. G. Fielding Blandford: The Diagnosis, Prognosis, and Prophylaxis of Insanity. (Second Lumen Lecture.)

SOCIETY OF ARTS.—8 P.M. Captain Wiggins: My Recent Voyage in Siberia.

WEDNESDAY.—ROYAL COLLEGE OF SURGEONS.—5 P.M. Mr. J. H. Targett: Recent Additions to the Museum of the College.

WEST LONDON HOSPITAL (Hammersmith, W.).—5 P.M. Dr. Abraham: Parasitic Skin Affections. (Post-graduate Course.)

SOCIETY OF ARTS.—8 P.M. Mr. John J. Holtzapffel: Sand Blast Processes.

THE SANITARY INSTITUTE (Parkes Museum, Margaret-st., W.).—8 P.M. Discussion on "Combined Drainage from the point of view of Health, Construction, Administration, and Law," to be opened by Dr. John F. J. Sykes and Mr. Wm. Nisbet Blair.

THURSDAY.—ROYAL INSTITUTION.—3 P.M. Mr. E. B. Tylor: Animism, as shown in the Religions of the Lower Races (II.).

ROYAL COLLEGE OF PHYSICIANS, LONDON.—5 P.M. Dr. G. Fielding Blandford: The Diagnosis, Prognosis, and Prophylaxis of Insanity. (Third Lumen Lecture.)

FRIDAY.—THE SANITARY INSTITUTE (Parkes Museum, Margaret-st., W.). 3 P.M. Subject of Lecture: Water.

THE CANCER HOSPITAL (FREE) (Fulham-road, Brompton, S.W.).—4 P.M. Mr. E. Cotterell: Excision of the Rectum.

ROYAL COLLEGE OF SURGEONS.—5 P.M. Mr. J. H. Targett: Recent Additions to the Museum of the College.

ROYAL INSTITUTION.—9 P.M. Lord Rayleigh: Argon.

SATURDAY.—ROYAL INSTITUTION.—3 P.M. Lord Rayleigh: Waves and Vibrations (VI.).

METEOROLOGICAL READINGS.

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

UNDER no circumstances do the Proprietors authorise the insertion of loose advertisement circulars and handbills in THE LANCET. Any such announcements are inserted by the newsagents, whom the Proprietors cannot control. At the same time, the Manager will be glad if readers will send him copies of any circulars, with the name and address of the agent through whom they obtain THE LANCET, and the Manager will then endeavour to mitigate the nuisance.

INFANTS' MIXTURES.

An inquest was held recently at Sheffield upon the body of an infant whose mother, it came out in evidence, was in the habit of giving her children "infant's mixture" at night, whether or no, apparently, there was anything the matter with them. The coroner, according to the *Leicester Post*, made some very strong remarks, with which we quite agree, and the verdict was "Death from natural causes, probably convulsions," a ridiculous and inconsequential verdict which suggests that no medical witness was called.

Matter of Principle.—From the facts supplied by our correspondent we have no hesitation in saying that: (1) he should have been asked by the other practitioner to see the patient; and (2) he did right in refusing to attend the case further.

ROWLANDSON AND HIS WORKS.

It is not very long since (Feb. 16th) we commented on the curious manner in which Rowlandson, in attempting to portray a particularly hideous man or woman, frequently foreshadowed the faces of acromegaly—a disease in his day entirely unknown to medicine. Messrs. Pears and Co. have chosen as the subject of their pictorial quarterly "Rowlandson and his Works," and the accuracy of our remark will be seen by all medical eyes. The figure in the plate representing *Avarice*, the male spectator in the picture entitled *A Six-in-hand Team*, both combatants in the picture entitled *A Fencing Match*, and the candidate in the picture entitled *A Theatrical Candidate*, all present to a remarkable degree the characteristically distorted features of the disease. The reproductions of Rowlandson's works are very well executed in this interesting publication.

W. J. H.—It cannot be wrong to visit a friend as a friend, though our correspondent is no longer the medical adviser. If the possible difficulties about such a visit are made quite clear to the patient, it seems to us that conversation concerning the medical aspects of the case and their present treatment could easily be avoided.

Dr. Robertson.—The Pasteur-Chamberland filter was described on page 259 of THE LANCET of Jan. 26th, 1895.

"A QUESTION OF DOOR-PLATES."

To the Editors of THE LANCET.

Sirs,—With some interest tempered with amusement have I read two letters in your last issue purporting to be replies to the question I asked you as to "the legality of the use of foreign unregistrable M.D. degrees alone on door-plates without other affix." The first, from a "Registered Foreign Graduate," occupies nineteen lines of your space in discussing points nowise germane to the matter under discussion. It is true he considers the editors "satiated of it"—and no wonder, if "Registered Foreign Graduate" represents the full strength of the foreign graduate element. To "M.R.C.P. & M.D. duly registered" somewhat similar remarks may fairly apply, as he also has missed the point of the original communication as to the continued presence on a door-plate of an unregistrable M.D. alone without distinguishing affix—the right being challenged. Dr. Critchley's letter is of a very different type, although he will, I hope, forgive my pointing out that it hardly replies to the question and is rather involved. The *crux* of the matter is: Is a medical man—A. B. by name—holding a registrable licence to practise, but not a registrable degree, entitled to place on his door, sign himself, and allow himself to be addressed "A. B., M.D." on the strength of having taken or purchased a foreign M.D. degree, which is not registrable? The reply can be given by you, Sirs, in few words.

I am, Sirs, yours faithfully, H.

March 25th, 1895.

*. The foreign source of the degree ought to appear on the card or plate, as a matter of candour. But we are not quite so clear as our correspondent seems to be as to the illegality of not stating it. The legal offence under the 40th section of the Medical Act is that of using titles which falsely imply registration. But in the case supposed the person is registered in virtue of other qualifications than his degree, which are just as good for registration purposes as a British degree.—ED. L.

THE CASE OF MR. C. BRYAN TOWNSHEND.

The following additional subscriptions are hereby thankfully acknowledged:—

Surgeon-Maj. De Tatham (London)...	£1 1 0	Mr. J. Cuthbertson Walker (St. Austell) ...	£0 10 6
Mr. Thomas Smith (London)...	10 10 0	Dr. and Mrs. Mutch (London)...	0 10 0
Dr. W. M. Kelly (Taunton)...	1 1 0	G. V. S. ...	1 1 0
Dr. Henry T. Sylvester (London)...	5 5 0	Mr. E. G. Cuthbert F. Atchley (Bristol) ...	1 1 0
Sympathiser ...	0 10 6	Mr. Alfred Emsom (Dorchester) ...	1 1 0

Further donations are earnestly requested, and will be acknowledged by the Rev. H. Townshend, 41, King Henry's-road, South Hampstead, N.W.

STRUCK OFF THE REGISTER.

The following small circular is being circulated among shops and public and private houses. On the door, we are informed, is a wooden board with "Dr. Costelloe" painted on it. We do not see any one answering to this address in the Medical Register. The General Medical Council at its last meeting ordered the removal of the name of Daniel Costelloe for covering an unqualified practitioner at Croydon and Belhurst (Minutes, 1894, Dec. 5th).

"Dispensary and Consulting Rooms, 23, London-street, Greenwich. Surgery hours: morning, 9 to 12 o'clock; evening, 6 to 10; Sunday evening, 8 to 9.30. Messages may be left at any hour, but patients are requested whenever possible to send before 12 A.M. Dispensary fees. Midwifery cases are attended at a reduced fee. Vaccination with calf lymph only. Teeth extracted."

Prochiral.—We think the appointment should be held in the name of an individual member of the firm.

MEDICAL ADVERTISING IN MANCHESTER.

THE following card is a study in the degenerated methods of practice which have multiplied of late. The absence of a name does not much excuse or extenuate the author of the card, whose personality is said to be well known. Similar documents are said to be common in Manchester. The card should be forwarded by the gentleman's neighbours to the bodies who are responsible for his diplomas. Does the author mean the public to infer by the words "a physician or a surgeon" that there are two persons responsible for this dispensary?

"The General Dispensary, 109, Upper Moss-lane, Manchester (established for the benefit of the middle and working classes during illness). A physician or surgeon attends daily—morning, 10 to 12; afternoon, 3 to 4; evening, 6.30 to 9; Sunday morning, 10.30. Terms: Advice and medicine, 1s., or 2s. per week; visits to patient's home, 1s. 6d., or from 3s. 6d. per week, payable in advance. Vaccination from calf lymph every Tuesday. Patients requiring to be visited are requested to give notice before 12 o'clock."

T. W.—We do not give medical advice and we never recommend individual practitioners. Our correspondent's condition is one that is very familiar to medical men; and it is in all probability the fact that on account of his avocation he cannot obtain rest and a definite or prolonged course of treatment that is answerable for the obstinacy of his case.

Mr. J. C. Bhattacharji should write to the Military Secretary, India Office, Westminster. The rules and conditions under which admission into the Indian Medical Service is gained will be found in the Students' Number of THE LANCET, published each year in September.

CLUB CHARGES.

To the Editors of THE LANCET.

Sirs,—(1) A large fishermen's protective society wishes to draw up a fixed rate of charges for medical attendance. What would you consider fair for visit and medicine, for visit only, and for medicine only? (2) A girl of twenty-two years has been suffering for the last seven years from oedema of the lower extremities, with occasional attacks of phlebitis. Everything imaginable has been tried. May I ask the advice of your readers, some of whom may have seen a similar case?

I am, Sirs, yours faithfully,

March 25th, 1895.

R. I. T. A.

*. We regret to be unable to advise our correspondent, but the information given us is too scanty. The tariff should obviously bear due relation to the wages of the fishermen, to the numbers who would belong to the proposed society, and to the strictness of the regulations against the admission of comparatively well-to-do persons as fishermen. If our correspondent can give us further particulars on these points we will attempt to assist him from our knowledge of the fees paid by members of similar clubs. We leave the second question to our readers.—ED. L.

THE STUDY OF EVOLUTION IN WHITECHAPEL.

ONE English lady has evidently profited by the writings of Haeckel. She did not want to be evicted, and so she produced a fetal kitten, saying she had had a miscarriage. Early embryos are very much alike, and the medical man accordingly gave her a certificate to that effect; but another discovered the fraud, and so the lady had to go. She may console herself by posing as a nineteenth century Mrs. Tofts, who made her name by producing a brood of rabbits. Students of Hogarth will remember his picture, "Superstition, Credulity, and Fanaticism," where the incident is represented in a vivid manner.

Colonist is advised to write to Dr. Chas. Gage Brown, C.M.G., Medical Officer to the Colonial Office, Downing-street, S.W. He will also find some information in the Students' Number of THE LANCET, published every September.

ERRATUM.—In the report of the deputation from the Sanitary Inspectors' Association to the Local Government Board, which we printed last week, Sir Walter Foster was made to refer to the year "1864" as the date of "the least fatal of previous [cholera] invasions." The date mentioned by Sir Walter Foster was, of course, 1866.

During the week marked copies of the following newspapers have been received:—Irish Field, Bolton Chronicle, Medical Record, Hampshire Telegraph, Man of Ross, Cork Daily Herald, Glasgow Herald, Derbyshire Courier, Wallasey Chronicle, Denbigh Free Press, Sussex Daily News, Huddersfield Examiner, Scotsman, Sheffield Independent, Birmingham Mail, Carlisle Journal, Cumberland Packet, Stirling Journal, Macclesfield Courier, Citizen, Builder, Pioneer Mail, Leeds Mercury, Sun, Times of India, Architect, Yorkshire Post, Lincolnshire Chronicle, City Press, Bristol Mercury, Mining Journal, West Middlesex Standard, Hertfordshire Mercury, Courrier de la Presse, Local Government Journal, West Middlesex Advertiser, Surrey Advertiser, Guy's Hospital Gazette, Nottingham Daily Guardian, Ormskirk Advertiser, Burton Chronicle, Bath Herald, Evening Citizen (Glasgow), Guernsey Advertiser, Edinburgh Evening Dispatch, Craven Herald, Littlehampton News, North Wales Guardian, Grimsby News, Sevenoaks Chronicle, Dundee Advertiser, St. Mary's Hospital Gazette, &c., &c.

Communications, Letters &c. have been received from—

ON

THE DIAGNOSIS, PROGNOSIS, AND PRO-PHYLAXIS OF INSANITY.

*Delivered before the Royal College of Physicians of London
on March 28th and April 2nd and 4th, 1895,*

By G. FIELDING BLANDFORD, M.D. OXON.,
F.R.C.P. LOND.,

LECTURER ON PSYCHOLOGICAL MEDICINE, ST. GEORGE'S HOSPITAL.

LECTURE I.

Delivered on March 28th.

THE DIAGNOSIS OF INSANITY.

GENTLEMEN,—The diagnosis of most diseases is easy when we are face to face with a well marked and typical example, but in almost all there is from time to time a case which is not well marked and about which there is great doubt. It may be that time will solve the difficulty, and meanwhile we watch the patient and stand prepared for whatever result we may find, and our uncertainty may possibly be unattended by any evil consequence either to the sick man or to ourselves. In insanity also the diagnosis is easy in the majority of cases. We are not in doubt when we see the noisy raving or hilarious chattering of acute mania, the gloom of melancholia, or the fatuous silence of dementia. But there are others about whom we shall be consulted where the diagnosis will not be easy. It may be necessary to consider whether a man shall be placed under restraint "for his own or for the public safety," or to prevent him squandering his fortune and impoverishing his family. He may have committed an offence, and we have to say whether he is responsible to the law; or he may be dead and we are no longer able to examine him, yet we are called upon for an opinion as to his capacity to make a will. In a great number of cases we cannot wait and let time come to aid us in our decision. We have to decide then and there, and if it is a question of placing the individual under restraint, it is one of the greatest importance both to him and to us. If we shirk the responsibility and leave him at large, homicide or suicide may follow, or he may be reduced to absolute beggary. If we sign a certificate without sufficient ground we may be assailed by an action at law. Many at the present time will not sign certificates; but in one way or other most men in practice are brought into contact with insanity, and cannot avoid giving an opinion upon some patient whom perhaps they are attending for another ailment, or who has done something which raises the vexed question of criminal responsibility, or has made a will which is disputed. It is of no avail to decline to give an opinion on such a matter. A *subpoena* will bring us into court, and cross-examination will elicit in perhaps an unpleasant way what we know or do not know about the subject. There are two processes or steps in arriving at the diagnosis of a case of insanity. First of all, there must be an examination of the alleged lunatic. To gain access to a patient is sometimes a very difficult matter, and may tax all our resources. I do not, however, propose to consider that now. Having interviewed the individual we have to come to a conclusion as to whether he is or is not insane. In very many cases there is no doubt about it. The symptoms are well marked and the need of restraint urgent, and without further delay a certificate of insanity is signed. In others we can decide with equal confidence that a certificate cannot be signed. But here and there we meet with a case which admits of doubt and is not urgent. We can go home and think it over and consider whether it falls under one or other of the varieties of insanity which are described in books, or of which we have had previous experience. I purpose to bring some of these before you, but prior to so doing I would say a few words as to the origin and conditions of mind disorder which may throw some light on the diagnosis to be made.

In the sane and healthy mind the highest brain centres, the seat of the highest feelings, reason, volition, and memory, work harmoniously in ordered action and reaction in a sane and healthy body. But if anything interferes

with the healthy working, the highest brain-centres, those which are the latest evolved and the least organised, will be the first to show symptoms of strain or fatigue, and will be, to use a modern but well recognised phrase, "reduced." Then the lower impulses are not controlled as they should be by the higher. The higher, which by some are called the "altruistic sentiments,"¹ by others the "relational feelings" or "object-consciousness," are weakened by the diminished functional activity in the realms of the cerebrum correlated thereto.² The egoistic feelings, or subject-consciousness, rise in proportion, the patient becomes more and more selfish, indifferent to the wishes and wants of others, takes no pleasure in the society or pursuits of others, even those of his own family, neglects his business, and in all outward relations is an altered man, while at the same time he displays an equal alteration in himself, in his egoism, his indecision and general failure of mental power. The decline of the highest mental attributes, and the rise of the lower egoistic, the self or subject-consciousness, are noticeable throughout all the stages and varieties of insanity. It is hailed as a good sign if a melancholic patient will so far forget himself as to ask after his family or children. The general paralytic at the opposite end of the scale boasts of the asylum being his palace, and proclaims his personal strength when he cannot stand without assistance. The self-feeling has no check and no control from the higher centres, which become more and more enfeebled from the progress of the disease.

When we turn to the origin and causation of mental disorder we see at once how much more prone are some to such rise of subject-consciousness. There are many who by reason of a faulty inheritance are egoistic throughout life. Selfish at school, they are selfish when adolescent. They are selfish in their love-making, and if in consequence they are unsuccessful, their pride is mortified and perchance their head loses its balance. Their religion is all self. Either it proceeds from self esteem, and a pharisaical wish to pose as better than others, or from fear of what will happen to them hereafter. Then, again, how many do we see whose whole life is devoted to the gaining of wealth? Some strive to attain this object by increasing attention to business. Their whole day is given up to making money, and if anything goes amiss and they make a small loss instead of a profit, it affects them in an extraordinary manner. Others are excessively penurious and try to amass a fortune by stinting themselves and those about them in every conceivable way. One gentleman, a patient of mine, used to invest every penny that he could to add to his income, and when he had reduced his balance at his banker's to such a point that it was inconvenient, he tore his hair, became melancholic, declaring that he was ruined and could not pay his debts. His income was about £3000 a year. How often do we see in those who inherit the insane diathesis the constant presence of suspicion. This often makes its appearance in the relatives of patients. They go from medical man to medical man trying to test the opinion of one by that of another. They place their relative under our care, and if he does not get well in a week or two they forthwith suspect that we are not trying to cure him, that we are trying to keep him for profit, and so on. These people suspect not only the medical man, but everybody. Everyone has an object in what they do or say. They suspect their clergyman, their lawyer, their friends. They listen to every tale of their servants or the gossip of a village, and embitter their lives by their suspicious fancies. Another form which is not uncommon is jealousy. This may range from the jealousy of boys and girls, manifested at a very early age, to that which makes wretched the life of married people and often approaches very near to insanity. Amongst the young it is one of the manifestations of intense egoism. Their friends must have no other friends. The boy or girl is jealous if anyone comes between him or her and his or her especial comrade. It is the same in later life, though more frequently seen in women than in men. In large families great jealousies often exist amongst the members; and in married life incredible jealousy is to be found without any other sign of insanity. Men and women think their wives or husbands are running after others or looking at others without the faintest ground for such suspicion; many a home is thus rendered miserable, and the step towards insanity is not a long one, though such insanity is often difficult to certify. Another variety of the insane temperament is excessive nervousness or fear. I do not mean that every lady who is

¹ H. Spencer.

² Bevan Lewis.

afraid of a cow, or shrieks at the sight of a mouse or a black-beetle, a toad or a rat, is likely to become insane. It is a kind of hereditary privilege of the sex to have a horror of such objects, but we see women—aye, and men, too—who are fearful of things quite as ridiculous, afraid to go in a train, afraid to drive, afraid of this, and afraid of that; let one of these get out of sorts, depressed by influenza or the like, and he straightway imagines that everyone is plotting against him and conspiring to kill or ruin him. If reassured by change of scene and people he may rapidly recover and return to his normal condition, which we may call "pantophobia"—fear of everything. Then there is hypochondria, which often merges into insanity. This is another form of fear. Patients are so afraid for their health, and so wrapped up in the task of taking care of it, that they can do nothing else, and neglect their business and family in the vain search for remedies for imaginary ailments. All these egoistic people are prone to insanity, but the diagnosis is difficult, for the insanity grows out of the inherited temperament, and it is not easy to say where the one ends and the other begins, or to fix the point where the normal must be considered to have passed into the abnormal.

Far easier is the diagnosis when we find that instead of an exaggeration of the natural character of the man a total change has come over him and he is altered in every way—in habits, disposition, and feelings. In many a certificate we read that the patient is "totally changed," and no better symptom of insanity can be adduced than such a change if we are so circumstanced that we can mention it as a fact. Now it is clear that patients whose whole condition is altered by mental disorder must have their nervous system far more "reduced" than those whose insanity is only an exaggeration of their previous state and whose "reduction" is comparatively slight. The latter being persons with an insane diathesis, a very small matter suffices to throw them off their normal balance. They are the cases where the friends tell us that they can in no way account for the attack. Such people for the most part have a history of heredity. They break down, perhaps without any apparent reason, recover, and break down again, and pass often into a state of recurrent insanity which may last through a long life. In the patients whose character is totally changed we more often find an adequate cause. Long-continued overwork or worry has reduced the health of the brain cells, or bodily illness, such as influenza, has undermined the nervous force of the individual, and insanity, chiefly of the depressed kind is the result. This does not pass away speedily, but is often very tedious, a long uphill process of repair being required to bring the nerve power to its normal level.

Whether the reduction be an exaggeration of the individual's peculiarities, or a total change of habits and character, if it only goes deep enough we find sooner or later delusions. Delusions aid us much in the diagnosis of insanity, especially for the reason that they do not appear at the commencement of the disorder, but indicate that it has existed for a certain time and proceeded to a considerable depth. Many patients suffer from simple melancholia without definite delusion. They are depressed, out of spirits—they cannot tell why. Their business, or even their amusements, are a nuisance to them. They dislike seeing their friends, and even writing a letter a bore, and are often irritable to those about them in a way they never were before. But as yet there are no distinct delusions. Conversely, patients will display a state of exaltation and of change in this direction without delusion. They talk in an excited and rapid way, much more so than is their wont. They are inclined to speculations, they build new houses or buy things they do not want, are inclined to quarrel, and by no means willing to take advice. They sleep but a short time, rising very early and expecting others to do the same, and their whole conduct is foolish, often causing in their friends a fear that they have been giving way to drink. But all the time there may be no delusions. In the latter class of cases insane conduct generally precedes delusions because the patient is active, restless, and eager to be doing something. In the former delusions generally come earlier, and we have less difficulty in diagnosing insanity and taking the necessary steps for protection, the depressed person being for the most part more docile and more easy to deal with. That the delusions of the depressed grow out of their condition of nerve prostration is recognised by many observers, and according to the idiosyncrasy of the individual they will arise early or late.

In many the self-consciousness which I have already mentioned is a prominent feature and comes readily to the surface. Such people are timid, fearful of criticism, and distrustful of others. They feel great depression of spirits, for which they cannot account. They may at the same time feel bodily discomfort, with pain in the head, indigestion, and constipated bowels. Notwithstanding they imagine that their food is poisoned; at first, perhaps, they think only that it has been tampered with, or that unwholesome provisions have been supplied; then that poison has been put in it by some person or persons known or unknown. Feeling themselves peculiar and changed, they think that the people in the streets look at them, then that they point at and deride them. Next they fancy that the newspapers write about them, and that all the mysterious advertisements refer to them. There is a plot and a conspiracy to rob, ruin, and destroy them, and they try to run away from it and hide themselves from their enemies. Here it is evident that there is a complete loss of adjustment between the environment and the patient. Instead of living in harmony with his surroundings he dreads them and would flee from them. How does all this affect our diagnosis of the case? Our diagnosis is for the purpose of treatment, for legal restraint, or legal interference with a man's property and business. The depression I have spoken of demands in the first place treatment, and this is often efficacious. Mere removal, with change of scene and surroundings, I have known to be sufficient to allay the fear with which the sufferer is overwhelmed. Having conceived the idea that those about him wish to poison him, to mock or ruin him, he feels the utmost relief when removed from their reach and finds himself surrounded by others in whom he has every confidence. More than once I have known patients escape from those placed to guard them, escape to friends or acquaintances, and then recover by the feeling engendered through the new set of surroundings. This is the reason why in almost every case change of scene does good, though possibly only for a time. It is the reason why almost every patient is better when first admitted into an asylum, though the improvement may not last long. The reduction of the brain centres may become deeper and the delusions increase. The patient will be afraid of his new-found friends after a few days, or will think that his former enemies can reach him in his new abode. Then, as his subject-consciousness becomes more and more developed, and his self-feeling intensified, being always pervaded by the nerve depression, he thinks not only that all his environment is conspiring against him, but that all is wrong with himself. He has done wrong, has neglected his business and ruined his family, or has robbed his partner or employer; he has committed the unpardonable sin, the sin against the Holy Ghost, and is eternally lost and about to suffer torments in this world or the next; or he has some loathsome disease, as syphilis or leprosy, or is about to have hydrophobia because perhaps a dog licked his hand some years ago. All such patients come before us for treatment, and our diagnosis will be largely influenced by this—that all such people are to be looked upon as suicidal. It is difficult to say when a patient may begin to be suicidal. Some will commit the act, or attempt it, when only a very moderate degree of depression has been noticed, and their friends will express the greatest surprise at their so doing. The diagnosis is difficult, but we may render it easy if we choose to treat all melancholia, however slight, as suicidal, and insist on a patient not being left alone. When such advice is given we meet with the greatest opposition from the friends. Not long ago I told a lady of high rank that her daughter was suicidal and required attendants. She said she was not going to have such people in her house for her servants to see and know. In a week or so her daughter threw herself out of a top window into a flagged yard and was killed on the spot, and instead of attendants the mother had an inquest to face. People shrink from watching a man in his own house and say he will not like it; and, in spite of advice, he is allowed to go out alone to buy revolvers or throw himself into the river or under a train. Suicide is very hereditary, and our diagnosis may be assisted by the knowledge that the ancestors or other members of the family have shown the same tendency. Many patients will openly threaten it, and it is a popular belief that those who talk about it will not carry it out. Unquestionably many who talk about and threaten it have not the slightest intention of committing suicide. They do this to frighten or worry their friends, or they make feeble attempts, such as scratching their throats or making small cuts on their wrist; but many who talk

about it have done it at last. They may for a time have sufficient self-control or fear of death, but as the malady advances this is overcome. One week a patient may say he would not do such a thing, or is afraid lest he should do it, and the next he commits the act. Men commit suicide in far larger numbers than women, but I am inclined to think that women make attempts or pretences of suicide in greater numbers than men, but have not the courage to effectually accomplish it. Depressed patients require care and treatment for this reason, and another is that all except those in a state of extreme delirious melancholia are exceedingly amenable to treatment and recover in larger proportion than any other class of the insane. Recoveries are on record where the patients have been melancholic for years. I myself have seen two who recovered, one after thirteen and the other after fifteen years, and several I have known were in a state of extreme depression for five, six, or seven years. I do not think that any suffering from chronic mania with delusions or hallucinations ever recover after so long a time. In the case of the latter the reduction, I imagine, is greater, and an organic change takes place which does not occur in the melancholic. In the latter it appears as though there was a defect of nerve force which causes the feeling of intense depression, and out of this feeling the delusions spring; but the cells of the brain and their connexions, though they suffer from want of power, are not thereby damaged, and are ready to resume their healthy working when the needful force is supplied. And this is borne out by what we notice in so many of the depressed. Apart from the melancholy and the delusions engendered by it, they can converse rationally on any subject. There is no loss of memory, of attention, or of judgment in matters not pertaining to themselves. One gentleman whom I saw daily for five years had various delusions, but he was thoroughly up in all that was recorded in the newspapers and would discuss it with excellent sense and judgment. A pleasanter companion I could not wish for. He recovered after being for seven years in an asylum. It is this mental power which so often deceives the friends and even the medical attendant. They shrink from placing such a man in an asylum; but a man who is tolerably composed and will talk excellent good sense in the evening will very likely wake the next morning in the blackest despair, and that is the time he is most likely to commit suicide. There is one golden rule: that such persons shall never be left alone. Whether in or out of an asylum, this should be enforced, whether they like it or whether they do not.

Far different is the state of those who suffer from mental exaltation. This will vary much—from excitement of a kind which can hardly be considered insanity to the hilarious delirium of acute mania. I am not here to discuss the pathology of mania or melancholia, but I cannot help thinking that in the former we have an opposite state of things—that there is an over-action of the brain circulation due to the failure of the centres which control it. This over-action is shown in the flushed face, the quickened pulse, the general "explosiveness" of the maniac. Here, more perhaps than in melancholia, we remark the "alteration" of the patient. His highest centres are "reduced," and very much "reduced." Judgment, reasoning, and attention are all in defect. If we engage such a man in conversation he cannot keep to the point; he will commence the answer to our question, but soon wanders off; his ideas have no coherence, and we write him down as incoherent. There may as yet be no delusion, but it is impossible to say that there is no defect of intellect. His every act betokens that his highest cerebral centres have lost control, and the lower and egoistic self-feelings are carrying him along in an uncontrollable flood. The most typical cases of mental exaltation are the general paralytics. Their hilarity and self-satisfaction, the grandeur of their ideas, their extravagance of expenditure and delusions of wealth and magnificence are known to all. Yet these delusions point to a condition of brain for which there is no cure. Instead of the slow and defective action of the melancholic who recovers after years of insanity, we find a coarse brain disease which terminates life after a short time. It is evident that the pathological condition of the exalted maniac who is not a paralytic must be closely allied to that of the maniac who is; for the mental symptoms may be so much alike that the most experienced may be left in doubt if physical symptoms are wanting. There is at first the same alteration, the same moral perversion, the same loss of attention. They even begin in the same way by a stage of melancholic depression. This is very common in ordinary mania, but not so common

in general paralysis; yet I have known a case of the latter where melancholia lasted for a considerable time, necessitating care in an asylum. The patient recovered from this in the usual way and returned to his home and work and no one had a suspicion that the attack had been anything but ordinary melancholia till the symptoms of exalted general paralysis suddenly made their appearance. In another there was a long period of depression, from which recovery did not take place, but a gradual change whereby the patient passed from the depressed to the exalted, but demented, state of general paralysis.

In the case of a patient suffering from mental exaltation a diagnosis is necessary to determine, first, whether he is or is not insane—so insane as to justify interference with his liberty of conduct; and, secondly, whether the insanity is ordinary mania and probably curable, or that which is known as general paralysis and incurable. As I am speaking now more especially about insanity with delusions I will take the latter question first. There are many maniacs with exaltation and corresponding delusions who are not general paralytics. Some are under the delusion that they are descendants of some noble family and the rightful heirs of this or that noble house, and they lay claim to a title in accordance with the idea. They may have cards engraved with the title and coronets placed on their notepaper; others will imagine that they have discovered some wonderful invention which is to make their fortune, and on the strength of the riches which are to come they squander what they have in the most reckless way. I once was occupied for half a day in going round the town and countermanding the carriages and horses that one of my patients had ordered. Many tell us they are going into Parliament. If in the army they are to be made generals, if in the law they will be judges or Lord Chancellors. Exaltation of any kind will make us suspect that the patient is suffering from incipient general paralysis. I know nothing more difficult than the diagnosis here if physical signs are wanting—nothing more easy if they are present. By the time that exaltation has reached the stage of delusions the physical signs of general paralysis will be noticeable in the majority of cases if the disease is present. The expression of the face is often peculiar. The patient looks dull and demented when at rest, and abnormally excited when speaking, with twitchings of the facial muscles and general tremor. When asked to show the tongue he jerks it out and in with a kind of convulsion, and if we ask him to keep it out we notice a fibrillar tremor of the muscles of it. And besides the facial and tongue muscles, those of the lips will show signs of the disorder. There is a tremulous condition of the latter, said by Sir John Bucknill to be like that seen in persons about to burst into passionate weeping. In some this tremor will be noticeable, while in others we see a stiffness and unnatural immobility of the lips, especially the upper. And these affections of the lips and of the tongue bring about another symptom which is very characteristic of general paralysis—viz., defect in the articulation. This is a stopping or stutter in the enunciation of a word or the various syllables of a word, especially a long one. It is somewhat like the thickness of speech of a man who has had a little too much liquor, and many are thought to be in this condition if they are disorderly in public places. It may vary on different days; if a patient is speaking with an effort and loudly, he may get his words out clearly enough, but if he is excited and talking quickly and hurriedly, the defect will be conspicuous. Then there is another physical symptom very frequently present in this stage, which we call the second, or that of delusion; this is inequality of the pupils of the eyes. This, taken in conjunction with exalted delusions, is perhaps the most pathognomonic sign of general paralysis that we can find. There can be no question as to this. About the stammer observers may disagree, but if one pupil is larger than the other and is fixed to light, or contracts but little, it is almost conclusive. Sometimes both pupils are extremely small and contracted, do not alter under light, and may remain constantly in this state during the patient's life. The knee-jerk in the early stages of the disorder is generally exaggerated; later on it is altogether abolished in the majority of cases. There are often epileptiform attacks even in the early stage which may materially aid us in our diagnosis. And it sometimes happens that the physical symptoms may be more marked than the mental, and that we may be able to note inequality of pupils or want of reaction, difficulty in gait, or slowness of speech at a time when there is only an alteration in mind, when we are not

able to sign a certificate of insanity. I have seen two such cases within a short period. From time to time we see a case of acute alcoholism where there are such symptoms of dementia with perhaps some amount of paralysis, that we pronounce it to be one of general paralysis. We are greatly astonished to find improvement take place under proper treatment, and ultimately recovery. Did time permit I could give the particulars of an interesting example of this disorder.

In the insane we meet not only with delusions, but also with hallucinations—sometimes both coexist in the same individual. Hallucinations are extremely common in acute insanity, especially those of sight and hearing. In chronic insanity they are frequent, especially those of hearing; they characterise an important class of patients, and are symptoms difficult to remove and very prone to recur. They depend upon disturbance of the centres of the special senses, of those of general sensation, and visceral and sexual feeling. I am not concerned with the pathology or origin of hallucinations. For the diagnosis of insanity they are important, especially in the chronic forms, but they occur not only in the insane but also in the sane. Sometimes they are found in those suffering from acute febrile disorders, when they take the sound of church bells, or appear as rats or snakes around the patient in delirium tremens. People not in acute illness, but in feeble health, may see visions of cats or the like. And such visions may serve as a gauge, so to speak, of the individual's state of health. I have said that in acute insanity, especially acute mania, they are common. And those most frequently met with are hallucinations of sight. Patients see visions or faces or animals about them, angels or devils, or mere flashes of light or fire. The diagnosis in such cases admits, of course, of no doubt. The patient is in a state of acute insanity, and delusions and hallucinations abound, frequently changing, and being generally more marked by night than by day. It often happens that a patient waking from sleep is terrified by something he fancies he sees or hears, and he may attack the person or persons watching him with this idea. But as the acute attack passes away, the hallucinations, like the delusions, vanish, and recovery takes place. There is no difficulty in detecting such hallucinations or in recognising the symptoms of insanity. Neither will it be difficult to recognise the hallucinations which we may call visceral, or those where the disturbance is of cutaneous sensibility. Such troubles of sensation are loudly complained of, and the sufferer will seek relief in various ways and appeal to medical men or lawyers or the police in the belief that a conspiracy is set on foot to torture him by electric shocks or such like methods. When such hallucinations exist in a chronic state, we are not likely to mistake them or under-estimate their significance. Far more frequent amongst the chronic insane are hallucinations of hearing—hearing "voices," as they are often termed. These are very common and very formidable, often incurable and hard to detect. But for these "voices" such people may be in all respects sane, and conduct themselves as ordinary members of society, yet are they always to be looked upon with suspicion. One day they may be able to control themselves and to disregard the "voices," the next they may feel bound to obey the voice and do what it commands them, whether it be homicide or suicide. It often happens that a patient will not reveal what the "voices" say, or confess that he hears them at all, and our ignorance of the hallucination may make it very difficult for us to arrive at a diagnosis or account for the patient's peculiar conduct. I once saw a lady whose conduct was manifestly insane, and who, when alone, was excessively noisy, but no one could detect any delusions. Her noise ceased when anyone entered the room and she would give no explanation thereof. By watching her without her knowledge through the crack of the door I saw that she was talking to imaginary people up the chimney, and was evidently greatly enraged at what she was hearing from them. She ceased when I entered the room, but admitted the hallucination, and I was able to sign a certificate. Such patients are dangerous for two reasons. They may think themselves bound to obey the voice, whatever it may direct. They will hold it responsible and themselves irresponsible, and they will feel themselves equally bound to conceal what passes, and will deny that they hear any voice at all. We may sometimes detect them by noticing that the patient, while we are talking to him, is inattentive to us, and evidently listening and trying to catch something which he hears going on. This he may or may not communicate to us. But there are other patients who hear voices and are dangerous for another reason. The voices often torment them and make

their lives intolerable by the accusations they bring and the crimes they allege. All the delusions which we find in a melancholic patient are in the hallucinated converted into "voices." From the next house, through the walls, the floors, or the ceiling, these voices perpetually resound, calling the sufferer the foulest names, accusing him of unnatural offences and everything that is vile. The patient does all he can to avoid the persecution. He flies from house to house, from country to country. One lady I knew bough: the next house to her own whence the voices proceeded and turned everyone out of it. Needless to say, the sounds went on as before. She made it a solitude, but she did not procure peace. And not only in the house does this persecution go on. In the streets and public places the passers-by launch obnoxious epithets at the individual, and when we hear of a person being shot or attacked by one wholly unknown to him, we may have a reasonable suspicion that "voices" are the explanation of the assault. If there is a forensic contest and hallucinations are adduced as evidence of insanity, we shall be told that sane people have hallucinations. It is quite true that persons who are not insane in the ordinary sense have hallucinations both of sight or hearing if they are out of health or are suffering from an acute attack, whether it be delirium tremens or some febrile disorder. But nobody can pretend that there is nothing wrong with the brain of such patients. For the time, at any rate, their brain and mind are disordered as much as is that of the insane person. Then we shall be told that various well-known people had hallucinations. Dr. Johnson heard his mother's voice calling "Sam" when she was far away; Lord Byron saw a spectre, Napoleon saw a star, and Cromwell a vision. We have nothing to do with these stories, which are very doubtful; the authority for them we cannot cross-examine. It is when hallucinations affect conduct that we are concerned with them, or when they are likely to affect it, for we cannot wait till a man assaults or murders another under the idea that he is insulted. Similarly with regard to delusions. Erroneous opinions are not insane delusions. There are people who believe in spiritualism and mesmerism, in homeopathy, and the like. There were many who believed that the "Claimant" was the real Tichborne. But these are not the delusions of the insane man, who believes in some fact which personally concerns himself and on which he is prepared to act in spite of all the reasoning and demonstration which is brought and put before him by others, friends or advisers, whose opinion he would undoubtedly accept were he in his right mind.

Hitherto I have considered those forms of insanity which are characterised by delusions and hallucinations, and the large majority of insane patients have delusions or hallucinations or both as the prominent symptoms of the mental disorder. There are some, however, whose unsoundness of mind, to use a comprehensive term, is shown by insane conduct rather than insane ideas, or who, by congenital or other defect, are unable to take care of themselves or manage their property or business. The first class, those whose insanity is characterised by insane conduct rather than ideas, are those to whose disorder has been applied the term of "moral," or "emotional," or "affective" insanity. The patients, it is said, are insane, but with an apparently unimpaired state of the intellectual faculties. Here, as in so many cases, there is beyond all question a very great dispute about words. One writer uses a word to mean a great deal which another does not, or the latter may use the same word in a totally different sense. Physicians are quite agreed that there are patients whose acts are insane, yet who have no delusions in the ordinary sense of the word. Every one can from his experience call to mind such cases, but controversy exists with respect to the name by which we are to designate them. If we lay aside for the moment the divisions of the mind such as intellect, emotion, volition and the like, and look upon it as the working of the highest cerebral centres which have been gradually evolved in ever-increasing complexity from savage to civilised races, and from the child to adult man, we see that according to the degree of evolution will be the complexity of feelings and the relations of feelings, and the composition and ideas of relations of which mind consists. There cannot be highly complex ideal feeling without equally complex intelligence. The highest mental attainment which civilised man can reach is a right rule of conduct regulating the affairs of life with judgment, prudence, and restraint. But if this standard is never reached owing to congenital defect or imperfect development or training, or if the highest centres are reduced by insanity,

or epilepsy, or alcohol, the mind is likewise reduced from a higher to a more automatic condition. There is over-action of the lower centres from the removal of the controlling influence of the higher. Applying this to conduct, we find that the reduced brain gives way to the gratification of the senses, regardless of consequences, permits indulgence in pleasure to the detriment of self or family, may set at defiance the conventional laws of society, or possibly the law of the land. The patient is reduced to the level of a child or an uneducated and untrained person, and the reduction may go on till it brings him to a level lower than that of a savage. This is no special variety. Any cause which operates injuriously upon the brain function may reduce the individual in this way. He is an altered man. He may possess a perfect memory, may be able to converse brilliantly, and argue keenly. He presents no delusion or hallucination, and yet his conduct is different from what it was before. He may not be immoral; immorality is only one form of this so-called moral insanity, but he is altered—and altered for the worse. He is wrapped up in self. The egoistic part of his mental constitution comes prominently forward, owing to the loss of the higher controlling centres. His affection and feeling for his wife, family, and friends are estranged; he is extravagant or penurious; he devotes his time and money to objects he would formerly have despised, or associates with people beneath him. This will go on for a time, and then he will get worse and descend to a lower level of delusion and more marked insanity. From this he may recover, to reach again the level of alteration, but he will never regain perfect sanity. He remains an altered man, altered in feelings to those he loved best, altered in habits, character, and conduct. He presents the spectacle of a half-cured patient. Nowadays, as soon as a patient is somewhat better, the friends clamour for his release from the asylum or restraint in which he has been placed, and those who have the care of the insane, whether officials or others, are prone to release patients, owing to such popular clamour, as soon as improvement reaches a certain point. Consequently, many who might have been cured by longer care and treatment are turned out to take care of themselves in the world at large and to remain half cured for the rest of their days. I have come across various patients in my own experience who were well-marked examples of this insanity without delusions. Two were men who had given way to drink and were in fact cases of chronic alcoholic insanity. They were both men of some amount of brain power, and a casual observer might say after an hour's pleasant conversation that he could detect no intellectual defect in either. Both had recovered from a lower level of insanity, from melancholia with delusions. One had a constant desire to return to drink, was dirty in dress, a collector of stones and rubbish with which he decorated his rooms, furiously passionate if thwarted, and quite without self-control. The other, under the garb of religion, was a liar of the most ingenious kind. His delight was to breed quarrels in the asylum, and to concoct letters of complaint to the Commissioners out of the quarrels and lies which he had concocted. No jury would have pronounced him insane, and only those who lived with the man could recognise how mad he was. Now if we are familiar with patients of this sort we recognise without difficulty or doubt that they are insane. But if we do not look at the patients in the concrete, but consider in the abstract moral insanity and such questions as what is morality or what is intellect, what is intellectual soundness or unsoundness, or whether a person can be intellectually sound and morally or emotionally unsound, we lose ourselves in a sea of verbiage and can satisfy neither ourselves nor anyone else. Just the same difficulties have arisen in applying the well-known legal test of the responsibility of the insane. We have heard and read a good deal about this lately; that to be irresponsible an insane person must be incapable of knowing right from wrong, or knowing the nature and quality of his act. Here everything turns on the meaning of the word *know* and its applicability to the accused person. To hear a judge solemnly charging twelve British common jurymen that they must decide whether an alleged lunatic knew right from wrong, and the nature and quality of his act, on a day perhaps three months previous—he being a man whom they have never seen before in their lives and never heard speak three words—would be grotesque were it not so serious. There is scarcely a dement in any asylum who does not know when he is doing wrong. He is deterred from doing it by the fear of consequences, knowing that his tobacco or his pudding will be stopped, or that something he dislikes will happen to him. He is an insane man, nevertheless,

and the system of rewards and punishments by means of which every asylum must of necessity be governed is one proportionate to the minds with which we have to deal, they being all alike in one respect—viz., that they are unsound, though in degrees they may vary much. The insanity of a man or woman in whom we can find no delusions must be shown by his or her conduct, and in forming an opinion we must examine the case as we would any other in other branches of practice. What is the history of the individual and his relatives? Does insanity exist in his forefathers or in any other members of his family? What has been his manner of life? Has he been intemperate, has he had epileptic attacks or apoplectic seizures? Is he altered, and, if so, how long has he shown signs of alteration, and have these increased lately? Close examination of one of these altered men may reveal to us the physical signs of general paralysis. Unequal pupils, the fibrillar trembling of the tongue, or the peculiar dull look of the face, will explain beyond doubt the nature of the change, and make a diagnosis easy which otherwise might be difficult. For the early stage of general paralysis is one which in many cases presents a typical moral insanity. The patient makes silly purchases, boasts in a silly way, is forgetful of times and appointments, drinks more than usual, possibly indulges in immorality or theft, yet no one act is unquestionably that of an insane man and no one idea is palpably a delusion.

I now pass to the consideration of another variety of insanity about which there has been much controversy. I refer to the so-called impulsive insanity which comes before us chiefly in cases of insane homicidal impulse. In our ordinary state of health an impulse to do something sudden or violent occurs to many. Some feel an impulse to throw themselves down from a height, or over the side of a vessel into the water. One person has a desire to scream out in a crowded church or theatre, another to smash something valuable on the table. All these impulses are by the healthy mind resisted and controlled; but when the mind is not healthy, when by disease the controlling power of the higher centres is inhibited, then insane impulse may be let loose in any direction—homicide, suicide, mere wanton smashing, or causeless violence. It is often urged that this impulsive insanity is something invented by medical men to excuse crime, but examination of patients and of recorded cases will reveal disorder of a very serious extent. There is a close connexion between these sudden impulses and epilepsy, and in more than one recorded case a well-marked *aura* has been known to precede the homicidal impulse. In others the latter appears to take the place of an epileptic convulsion, constituting what has been termed *épilepsie larvée*. And not unfrequently it follows, and is the result of, an epileptic attack, and of this both the patient and his friends may be ignorant, if it has occurred in the night when he has been sleeping alone. It also much resembles epilepsy in this, that it is not always present in the patient's mind, but is periodical, recurring like epilepsy without any special cause. Many are quite conscious of the feeling, and of their inability to resist it, and many have sought the assistance and restraint of an asylum, being unable to control themselves. In examining such a person we shall have first to consider the character of the deed, the mode of committal, and the absence or presence of motive. The act may be so motiveless, so contrary to the previous nature and feelings of the perpetrator, that no one can doubt it must have been that of a madman. It is not the amount of wickedness displayed in the act, but the senselessness of it that we are to regard. And even when the nature of the deed sufficiently stamps it as insane, we shall, if we seek diligently, generally discover other symptoms of insanity. The individual's history must be carefully examined, and the occurrence of epilepsy or insanity in the family noted. The time of life and condition must be taken into account, for instability of the nervous centres is specially liable to be exhibited at the periods of puberty or the climacteric, or those of pregnancy, parturition and lactation. Nor must it be forgotten that homicidal impulsive attacks may occur in other forms of insanity.

That caution must be observed in signing certificates of lunacy I need hardly insist on here, but in no class of cases ought greater caution to be used than in those where the insanity, or alleged insanity, is complicated by alcoholism. We have at present in this country no means of restraining inebriates but by confining them as lunatics under the statutory order, petition and certificates. As they are a terrible torment to their friends, and ruin their health and the property of themselves and families, as they are frequently violent to those about them both in language and in

act, and are often found wandering, lying in the gutter, and absent from home all night, the relatives seek our assistance and entreat us to sign certificates that they require care and treatment; but if we examine one of these individuals, what do we find? He may be drunk; but drunkenness is not insanity, and we must wait till he is sober; and then we may be able to detect no delusion or hallucination. He may deny most of what is alleged of him, and may be incensed with his relatives for calling us in. If we find enough in his history and in himself to warrant our signing a certificate, and he is sent to an asylum, this usually happens: drink is cut off, the man sleeps, his appetite returns, and in a very short time the asylum authorities are obliged to release him, and often the relatives are worse off than they were before. That there is an insanity from alcohol we know, but the insane symptoms of this are strongly marked and persist even when drink is stopped. If possible, I require that a patient shall be kept without drink for twenty-four or forty-eight hours before I examine him. It is of no use to examine a man in the middle of his potations.

I now proceed to the consideration of patients whose mental symptoms are not those of exaltation or depression, are not marked by hallucinations or delusions, but are characterised rather by enfeeblement and deficiency. These are of two kinds: those whose mental defect is congenital or the result of an arrest of development at an early age, and those who from former attacks, from coarse disease of brain or old age, have come to the condition which is commonly called "dementia." And first, of those who, through congenital defect or as the result of disease in early life, are mentally deficient—not idiots, but weak-minded imbeciles—children in mind throughout life. They come before us in various ways. Though children in mind, they are very often men and women in wickedness and vice; and it may be necessary to place them under restraint, or to protect their property from being squandered and themselves from being robbed. I know no class over whom controversy is so likely to arise, or where we may have greater difficulty in forming a diagnosis. They are not idiots; many of them have acquired a fair amount of education, can construe a Greek play, or master a proposition of Euclid. Their memory is excellent, and we cannot compare their condition with a former one; for they have never been any better, so that this test fails us. They have no delusions or hallucinations, and are not insane in the ordinary sense of the word. With regard to many there is no difficulty. When a man or woman of forty submits to be treated like a child of ten—to be taken out and amused, and to have sixpence a week pocket-money, we have not much difficulty in forming an opinion. But the development of others is not so low; yet they are deficient in reason and judgment, and often in conduct. There is a tendency to low and depraved habits, to brutish and sensual enjoyment, to low company amongst whom they are of more importance, and if remonstrated with they show an absolute disregard for truth or for right behaviour. Lawyers will defend these patients and say that they are not insane, and the celebrated Windham case shows what can be done by their aid. In examining any such individual we must consider his conduct in regard to his environment and bringing up. What might be passed over in the lower walks of life is in the higher evidence of a degraded mental state. Every case must be judged by itself, and the question must be asked, Is this person able to take care of himself and his affairs? But to sign a certificate is often very difficult, as we may not ourselves witness the insane conduct, all of which we arrive at only by hearsay. It is not to be forgotten, however, that imbeciles are very prone to display violent explosiveness of their nerve centres, and this is specially likely to happen as they advance from the period of puberty to adolescent life. "Last stage of all," there is the dementia of old age, of chronic insanity, or brain disease. In the vast majority of such cases the diagnosis presents no difficulties. Loss of memory, loss of attention, the mere oblivion and childishness, enable us to say that such a person is unable to take care of himself or his affairs, and never will be able. The prognosis is attended with as little doubt as the diagnosis. Here and there we see a patient whose dementia has not advanced very far, who varies a good deal, having good days and bad days, and is capable of being "coached" into giving tolerably rational answers to our questions. About such a one legal questions may arise and a forensic contest. If there is no urgent necessity it is better to wait. The dementia is sure to increase as time goes on, and a case which is difficult now may be easy enough to diagnose in six months' time.

TWO CASES OF ABDOMINAL SECTION ILLUSTRATING THE DIAGNOSIS OF TUBAL PREGNANCY PRIOR TO RUPTURE OF THE SAC.

By ARTHUR H. N. LEWERS, M.D. LOND.,
OBSTETRIC PHYSICIAN TO THE LONDON HOSPITAL.

CASE 1. *Diagnosis made of extra-uterine pregnancy prior to rupture of the sac; abdominal section; unruptured tubal gestation sac found and removed; recovery.*—A married woman aged thirty-five years was admitted into the Davis Ward of the London Hospital under my care on Feb. 24th, 1894, complaining of severe pain in the back and left iliac region. She had been married sixteen years and had had two children; the last was born fourteen years ago and is still living; the first, which was born ten months after marriage, only lived eight days. Both confinements were easy. She had one abortion when two months pregnant seven years ago. The catamenia appeared when she was thirteen years old. She menstruated regularly while suckling. She was quite well till about the end of 1893. At the beginning of 1894 she felt very sick and retched frequently, but there was no actual vomiting. About the same time she had severe pain, starting in the left iliac region, and extending round to the back and also across the lower abdomen on the right side. She was admitted into the Bromley Sick Asylum for three weeks from Jan. 19th, but was not relieved, and shortly afterwards was admitted into the London Hospital. The pain in the lower abdomen had been more or less constant both night and day; it did not shoot down the thighs, but was aggravated when the bowels acted. Besides the constant pain there had been occasionally since Christmas, 1893, severe pain in the left iliac region resembling labour pains and lasting two hours. She had had two intervals of a week since the beginning of the illness without pain. She had menstruated regularly up to Christmas, 1893, when the last period occurred. It lasted only three days, but the ordinary duration of the periods had been seven days. Since this period there had been no red discharge from the vagina till Feb. 12th, 1894, when she noticed a slight reddish-brown discharge, not offensive. This had continued up to the time of admission. She then continued to feel sick at times; this occurred in the night as well as in the day, and had no relation to meals. She was quite sure the breasts had been getting larger lately. She had at times recently experienced a sense of fullness in the left iliac region, but had not noticed any actual swelling there. On admission the patient was rather pale, but there was no marked anaemia. The pulse and temperature were normal, and the tongue was clean and moist. The urine was normal. On abdominal examination nothing abnormal could be felt. On vaginal examination the uterus was found to be uniformly enlarged, freely movable, and in the normal position. The cervix was soft and blue. A soft swelling about the size of an orange, but less definite in outline, was felt occupying the left side of the pelvis; it had a fair range of mobility. The sound was passed, and entered a distance of 3½ in. with the curve forwards. The breasts were firm and looked active, and fluid was easily expressed from both, that on the left side being distinctly milky. On March 3rd I examined the patient under the influence of an anæsthetic and dilated the cervix with Hegar's dilators up to No. 12. The uterus appeared, however, to be empty, and there was no history of anything solid having been passed before admission, nor was anything of the kind passed while she was in the hospital. Taking all the points of the case into consideration, it seemed to me to be a case of extra-uterine pregnancy in the left Fallopian tube, and I advised the patient to have an operation at once performed in order to remove the gestation sac before it should rupture. On March 8th, 1894, the abdomen was opened in the usual way. There was no blood in the peritoneal cavity. The uterus at an early stage came into view; it was of a purplish-red colour, very soft, and enlarged uniformly; in fact, its appearance and feeling were very similar to those of a pregnant uterus at about three months. On passing the hand down to the left of the uterus a soft swelling was felt about the size of an orange. It evidently contained fluid and was very thin-walled, for the manipulation needed to bring it up to the abdominal wound burst it and shot a foetus of about

three months' development out of the wound on to one of the mackintoshes covering the patient. The ruptured tube was held up, the broad ligament transfixed and tied with the Staffordshire knot, and a second ligature tied round the whole pedicle. The tube was then cut away. One or two separate pieces of placenta about the size of a penny came up on the sponges when the pelvis was being sponged out. The abdominal wound was completely closed with silk sutures. The subsequent progress of the case was uneventful and the patient made an uninterrupted recovery. The temperature never rose above 99.5° F., or the pulse above 94. The wound healed by first intention. The red vaginal discharge continued after the operation up to March 15th and then ceased. On April 2nd I examined the patient and made the following note: "Bimanually the uterus can be felt in a position of slight anteversion; it is little if at all enlarged, but a little less movable than normal." The patient was discharged on April 6th wearing an abdominal belt, and feeling quite well.

Remarks.—A certain number of cases have been published in which a tubal gestation, of the degree of development here mentioned, has been removed prior to rupture of the sac; but they are not very numerous, and any cases of the kind seem worth recording. The operation prior to rupture of the sac is a much simpler matter than when rupture has occurred, and the prognosis is that of a simple ovariectomy. It is far otherwise when an operation is undertaken after rupture of the sac. The patient may then be in a very feeble condition from the extravasation of blood into the peritoneal cavity, and on that account alone the risk of an abdominal section is considerably increased. There is also in some such cases great difficulty in thoroughly removing all the clot from among the intestines and the various recesses of the peritoneum; and if any portions are left there is a considerable risk after the operation that they may become septic, and so militate against the patient's recovery. In Case 2 recorded in this paper the first operation was undertaken under these unfavourable conditions, and her recovery from it was therefore tedious, forming a striking contrast to the uneventful recovery of Case 1. It is of the utmost importance, therefore, in the patient's interest, when the opportunity occurs, to make the diagnosis of extra-uterine pregnancy before rupture of the sac. The risk of operative treatment is then very small, while after rupture it is often considerable. A careful consideration of the history and of the physical signs will lead to a correct conclusion in a considerable proportion of cases. As regards history, the patient will generally be not younger than about twenty-eight or thirty, and will either have had no children or, at least, there will generally have been an interval of some years since any former pregnancy. She may miss a period, going some six or seven weeks without "seeing anything," and then some red vaginal discharge may occur and may be more or less persistent. Pain in one or other iliac region is also an important symptom. There may also be a history of gastric disturbance. Such a group of symptoms is extremely suggestive of extra-uterine pregnancy. The physical examination, especially under anaesthesia, if it shows that the uterus is uniformly enlarged and soft, the cervix blue, soft, and enlarged, and the presence of an elastic swelling in one or other side of the pelvis, is sufficient, combined with the history mentioned, to justify a diagnosis of extra-uterine gestation. Signs of activity in the breasts are also of considerable value. It is well to bear in mind, as has been well said by Mr. Lawson Tait, that absolute diagnosis within the abdomen is often not possible. Practical men will be content with such a strong balance of probability as is afforded by the history and physical signs given above. To refuse to act on that evidence is simply to wait in a considerable percentage of cases for rupture of the sac, and all its attendant dangers. There is an interesting point as regards the specimen removed in this case. There is, of course, at the outer end the largely dilated Fallopian tube that contained the foetus, then about an inch nearer the uterus there is a second dilatation of the tube forming a spherical swelling of the diameter of a half-penny; on section this, in the recent state, contained firm, dark-red blood-clot. It may possibly be a tubal mole, two ova having become impregnated in the same tube, the one forming the ovum that contained the three months' foetus and the other having become blighted and degenerating into a mole.

CASE 2. *Diagnosis made of extra-uterine pregnancy prior to rupture of the sac in a patient on whom I had operated for ruptured tubal pregnancy at the third month eleven months*

previously; abdominal section; actual condition, molar uterine pregnancy with ovarian tumour the size of a small cocoanut; recovery.—The case of this patient was especially interesting in that I had operated on her for ruptured tubal gestation in the spring of 1893. The case, so far as that part of it is concerned, is fully recorded in THE LANCET,¹ and I will only say that at that operation I found the peritoneal cavity full of blood and a foetus of about three months' development lying among the intestines. She made a tedious recovery after that operation, which I ascribed partly to the condition of extreme anaemia to which she had been reduced prior to it, and partly to my not having used a drainage-tube after it. She came to see me in October and November, 1893, and I examined her. There was nothing abnormal to be felt on examining the abdomen, and bimanually the uterus was found to be of normal size and in the normal position, but slightly less movable than normal. She menstruated regularly in October, November, and December, 1893. She also menstruated in January, 1894, from the 13th to the 17th, losing on that occasion a great deal more than at the periods in November and December. She consulted me again on Feb. 16th, 1894, on account of great pain in the left iliac region, of two days' duration. On simple palpation of the lower abdomen a swelling could be felt in the hypogastric region and also in the left iliac region, rising from the pelvis, and just about level with the pelvic brim. No such swellings existed when she was last examined in November. Bimanually the uterus was enlarged, less movable than normal, and an elastic swelling continuous with that felt in the left iliac region was felt in the left side of the pelvis. This could not be distinctly separated from the uterus. On March 4th I was sent for to see her and found that since Feb. 8th she had been losing blood in small quantities up to March 3rd; the loss then was considerable, and she passed two "lumps," one small and one large; these were kept for me to see, and were only blood clots. The pain in the left side had continued from Feb. 16th to the 27th, and then ceased. Since then to March 7th the patient had remained in bed. The reddish-brown discharge had persisted. Examination of the lower abdomen detected two swellings reaching to a level of four fingers' breadth below the umbilicus. The swellings were separated by a distinct interval in the neighbourhood of the scar left from the previous operation. On March 12th the patient was examined very carefully under an anaesthetic: the uterus was moderately but uniformly enlarged, the cervix being blue and soft; the swelling of the left side seemed to be fairly separable from the uterus. It appeared to me that the case was one of extra-uterine pregnancy, though the possibility of uterine pregnancy with a small ovarian tumour was thought of. Whichever it might be made no difference in the treatment, and I advised abdominal section. The patient was accordingly removed to Fitzroy House on March 13th. On the afternoon of that day an oval mass the size of a small egg was passed from the vagina; its outer surface was shaggy, and on section it had a central cavity lined by a smooth membrane, but there was no foetus. On examining the patient the swelling of the left side was felt as before, but the uterus was somewhat smaller and contracted. On opening the abdomen on March 14th the swelling of the left side was found to be an ovarian tumour the size of a small cocoanut; it had no pedicle and had to be enucleated from the broad ligament. Two pairs of Wells's forceps were left on bleeding points too deep in the pelvis for ligation, and a Keith's tube was inserted at the lower angle of the wound. The forceps were taken off in two days' time, and the patient made an uninterrupted recovery. A small sinus persisted for a considerable time till two silk ligatures came away; it then healed rapidly. I last saw the patient on Feb. 15th, 1895. She had not menstruated since the operation, and was getting much stouter. The uterus was in the normal position and of the normal size, and was freely movable.

Remarks.—There are some interesting points in this case in addition to the fact of the patient having been operated on for ruptured extra-uterine pregnancy eleven months before the operation here recorded. The oval mass passed from the uterus was undoubtedly a true mole—i.e., a blighted ovum; therefore, as the right ovary and tube had been removed at the first operation the ovum which degenerated into a mole must have been produced from the left ovary, which nevertheless had degenerated into an ovarian cyst the size of a cocoanut. On examining the specimen the left tube, a part

¹ THE LANCET, March 10th, 1894.

of which was removed with the ovarian tumour, can be seen to be open. Another point of interest is the time occupied by the degeneration of an apparently healthy ovary into an ovarian cyst of the size described. At the first operation, on April 22nd, 1893, there was nothing obviously wrong with the left ovary, yet by March 14th, 1894, it had become cystic, forming a tumour of the size mentioned. Whether its rapid formation was hastened by the occurrence of the molar pregnancy or not it is of course impossible to say, but on examining the abdomen in November, 1893, no swelling in the lower part of it could be detected; yet on March 7th, 1894 two swellings, rising from the pelvis and separated by a slight depression, were very easily felt there, the central one being of course the pregnant uterus and the lateral one the ovarian tumour.

Wimpole-street, W.

INTERSTITIAL KERATITIS AND SYNOVITIS, WITH REPORT OF A CASE IN WHICH BOTH WERE UNILATERAL.¹

By G. CRAWFORD THOMSON, M.D. DURH.

Literature on the subject.—It is only lately that a connexion between interstitial keratitis and synovitis has been recognised in England, although occasional remarks on the casual coexistence of both diseases may be found as far back as in W. Mackenzie's treatise and Hutchinson's earlier writings. W. Mackenzie,² in his classical description of what he called "scrofulous corneitis," mentions that sometimes with it "effusion into the bursa under the tendon of the extensor cruris" occurs. I have little hesitation in considering that the words quoted are meant to refer to the condition in question. Amongst fifty-three cases of interstitial keratitis published by Hutchinson in the first two volumes of the Ophthalmic Hospital Reports, 1860, swelling of the knee-joint is only once mentioned—viz., in Case 7, vol. i, p. 239. The patient is described as "a poor miserable looking child of bad, pale complexion." In his clinical memoir on Certain Diseases of the Eye and Ear consequent on hereditary syphilis in 1863 the former fifty-three cases are reproduced, and with them the case above referred to. On page 118 Hutchinson says that affection of the knee-joint was observed in three instances; but, as is clearly shown from the table of his cases, two of these instances refer to one patient (case 7), with double synovitis, while the third instance (ankylosis of the knee-joint, case 73) refers to a different condition altogether. Amongst the forty-nine additional cases (the memoir being based on 102) no further reference is made to the condition in question. I have not been able to find any other communication by Mr. Hutchinson on this subject between 1863-1886, the time of the publication of Heath's Surgical Dictionary. In his article on Hereditary Syphilis in "Reynolds's System of Medicine," 1866 the subject is not mentioned. In his two papers published in 1860-63 the connexion between interstitial keratitis and hereditary syphilis, as is universally acknowledged, has been first pointed out. A paper by Spencer Watson on four cases of parenchymatous keratitis associated with acute rheumatism,³ published in 1870, will be discussed later. The syphilitic synovitis due to the tertiary stage of the acquired and to the inherited form has been first fully described by A. E. Barker in his article on joint diseases,⁴ and the occasional occurrence of interstitial keratitis with it is here already mentioned. The first to draw attention to the close affinity of the two affections was Mr. Clutton in 1886.⁵ In his eleven cases both affections were bilateral, the joint affected being invariably the knee, there being only one case with previous swelling of ankles as well. As far as the etiology of the disease is concerned, the information is scanty, the history of specific disease being found only in four cases, no history in four, a doubtful history in one, and in two cases no notes were obtainable. In the same year as Mr. Clutton's paper appeared the connexion

between the two affections appears as a well-established fact, characteristic of hereditary syphilis, in Hutchinson's article on Hereditary Syphilis in "Heath's Dictionary of Surgery," and in 1887 in the same writer's manual on Syphilis. Nearly ten years before the appearance of Mr. Clutton's paper the fact was recognised and its pathological bearing fully discussed by Foerster.⁶ To him credit is due for having first observed the close clinical connexion between the two diseases, and for having first pointed out the non-rheumatic character of the joint disease.

Description of case.—Amongst all the literature which I have consulted (both English and foreign) I have not been able to find a case in which both affections have been and undoubtedly remained unilateral, therefore the presentation of the following case does not require further justification. In June, 1885, I commenced attendance on a girl fifteen years of age suffering from amenorrhoea and anæmia. She first menstruated at the age of thirteen, and her periods were regular until a year before, when she went to school. It was then that the menses became affected. Under treatment (iron and arsenic) she became much better in about six weeks. I did not see her again until the end of December, 1885, when I found she had relapsed into her former condition and was also suffering from inflammation of her right eye. In the beginning of January, 1886, she was seen by Dr. Julius Jacobson, who confirmed the diagnosis of interstitial keratitis made by me. The appearance of the cornea, which showed a diffuse greyish infiltration, containing some more saturated spots under a perfectly normal epithelium, advancing slowly from the margin to the central parts and surrounded by a dense ciliary congestion, was absolutely typical of interstitial keratitis. There was no deposit in the anterior chamber; the pupil was dilated perfectly by atropine. An ophthalmoscopic examination was not possible at this time. Warm fomentations and the continued use of atropine were ordered. Within a week afterwards effusion into the knee-joint, also on the right side, developed. The swelling was evenly distributed over the joint; the skin was of normal colour, not tense; painless, passive movement was not impeded; no nodes of tibia or enlargement of bones in the neighbourhood were to be detected; no loose bodies were to be felt in the joint; and there was no feverishness. I wrote to Dr. Julius Jacobson mentioning this, when he answered that the appearance of painless synovitis before, after, or with interstitial keratitis was by no means uncommon, and rather tended to endorse the previous diagnosis, at the same time adding that, both affections being nearly always symmetrical, we had to be prepared to see the other eye and joint affected in the same way. I may remark that his letter was written before the appearance of Mr. Clutton's paper, and that the connexion between the two affections pointed out by him to me was at the time completely unknown to me. It is needless to say that the suspicion of the case being one of hereditary syphilis presented itself at once, but a most careful examination did not elicit a single other symptom pointing to this disease. The teeth in particular were uncommonly well shaped, without any irregularity at all; the hearing was in no way impaired; there were no scars at the angles of the mouth or on the palate or mucous membrane of the mouth, no glandular tumours, no osseous swellings, no trace of any present or previous skin affection; the patient's regular and fine features showed nothing of the characteristic appearance of the skull; her nose was perfectly formed, and there was no flattening of the bridge. The examination of the body revealed nothing abnormal except a soft systolic murmur at the apex of the heart. Taking into consideration the extreme pallor of the face and mucous membranes, the general treatment resorted to was of a merely tonic character, including iron, arsenic, with plenty of milk, fresh vegetables, &c. At no time was either mercury or iodine given. Several attempts were made to reduce the swelling of the knee by strapping with Scott's dressing, iodine, and complete rest in splints, but without effect. It lasted about six months and then disappeared of itself, while the disease of the cornea ran its usual course, leading to complete infiltration of the corneal tissue and gradually clearing up from the margin after the onset of vascularisation. The eye had not regained its normal appearance until the beginning of 1887. During the whole time the general treatment was continued. At this date not only had the local symptoms disappeared, but a striking improvement had taken place in her general

health and appearance. Between then and now she has had occasional relapses into an anæmic condition, of which I have only seen one personally, as she took arsenic again on her own account whenever she began to feel unwell. She has been under my observation up to the present date and has developed into a strong, active woman, showing absolutely no trace of her former ailment, her complexion particularly being clear and healthy and her menstrual periods perfectly normal. She has never shown any disease in the other eye or knee or any other local mischief, so that the prognosis given at the time of the first examination has not been fulfilled. Dr. Jacobsen saw the patient again about four years ago. From the report then given to me by him I may mention here that there was slight hyperopic astigmatism in both eyes, after correction of which vision in the left eye was full $\frac{1}{2}$, while it was $\frac{1}{4}$ in the right; this slight diminution in sight was accounted for by an exceedingly thin central opacity of the cornea, only noticeable by focal illumination, in which examination with a strong magnifying convex lens still showed traces of bloodvessels so characteristic of the remains of interstitial keratitis. There were no opacities of the vitreous, no peripheral choroiditis, the pupil acted promptly to light and accommodation, and tension was normal. The previous history of the patient does not reveal anything pointing to hereditary syphilis. She had measles and whooping-cough when a child, but she was born perfectly healthy, and during infancy and early childhood had no snuffles, no skin eruption, and no throat affection; no bone lesions were noticed; in fact, up to 1835 she had been in the enjoyment of perfect health. I may add that I have had at different times the opportunity of questioning the mother as to the above-mentioned point, and that she is perfectly positive about the absence of any similar symptoms. The father of the girl died within the last year; he had been confined in a lunatic asylum for the last ten years of his life. From the medical officer I learned that the disease was diagnosed by Drs. Wilks and Savage as general paralysis, and that he had no direct evidence of syphilis. The mother is a strong and energetic woman, who has always been in perfect health, and has been confined fifteen times with the following results: (1) miscarriage at six months; (2) full time, crossbirth, died shortly after (unskilled attendance); (3) son, living; (4) daughter, living; (5) miscarriage at two months; (6) daughter, living (the patient); (7) miscarriage at two months; (8) son, living; (9) daughter, living, twin died at birth; (10) miscarriage; (11) daughter, living; (12) daughter, living; (13) son born healthy, died two months after birth from inflammation of lungs; (14) twins at seven months, died at birth; (15) daughter, living. An analysis of the above shows there were four miscarriages: Nos. 1, 5, 7, 10; one premature birth, No. 14 (twins); three children born at full time, but dying shortly after birth, Nos. 2 (unskilled attendance at birth) and 9 (one of twins dying and the other surviving); No. 13 (died two months after birth from inflammation of lungs); eight living children, Nos. 3, 4, 6 (patient), 8, 9, 11, 12, 15. With the sole exception of the eldest son, I have not only examined all the living children, but I have had them under observation during the last nine years, and am positive that not one of them has shown any trace of specific disease. In none of them the peculiar formation of head the broadening and flattening of the nose, the notched teeth, or any other symptoms of the kind are to be found.

Remarks on case.—Most cases described as one-sided interstitial keratitis are of little value, the time during which they are under observation being too short, as not rarely several years elapse before the onset of the disease in the other eye, but I am not aware that the interval has ever been as long as nine years. As my patient has developed from a delicate, anæmic girl into a perfectly healthy woman without any trace of former disease, I have no hesitation in regarding the case as being at an end, and, therefore, as one of undoubtedly unilateral disease and as one of the rare exceptions to the law formulated by Hutchinson⁹ that "interstitial keratitis in its typical form is always in the end symmetrical."¹⁰ In the best observed cases the effusion into the knee-joint has also been symmetrical, and probably the percentage of double-sided affection is still higher than

one would gather from reported cases, the absence of pain in mild cases blinding the patient to its existence. As said before, a case where both affections have been limited to one and the same side of the body is according to my knowledge unique." Certainly no explanation can be given why one side should be attacked in preference to the other, as otherwise no difference between the two halves of the body could be found. As to the causation of both affections I do not feel justified in attributing them to hereditary syphilis simply for the one fact that interstitial keratitis existed together with knee-joint affection. The history of my case, complete as it is, contains scarcely anything to suggest syphilis; only one point might be interpreted in this way—viz., the miscarriages of the mother. As regards this, the number and the time of occurrence are such as might be met in any woman free from specific disease, and it ought to be borne in mind that abortions are very common quite independently of syphilis, that there is every day proof that women may bear large families of tainted children and never show any tendency to abort—that, in fact, the part which syphilis plays in the causation of abortion is commonly exaggerated.¹⁰ This, taken together with the entire absence of any other sign of syphilitic taint in the patient, or of any sign in her mother, her sisters and brother,¹¹ all seen by me and under observation to the present day, leaves practically nothing which could be adduced as an argument in favour of specific disease. On the other hand, the girl at the time of her illness presented the usual symptoms of pronounced anæmia with amenorrhœa, appearing at the time of puberty and probably due to change of climate. It is in this lowered state of nutrition that, in my case, the cause of the affection of the cornea as well as of the knee-joint must be sought. Complete recovery took place under a simple tonic treatment, neither mercury nor iodide being given. In a disease with a decided tendency to recovery this latter fact is not of much value; still, it in some respects corroborates the view taken here.

(To be continued.)

ON THE VALUE OF EUCALYPTUS OIL AS A DISINFECTANT IN SCARLET FEVER.¹

By JOSEPH PRIESTLEY, B.A. LOND., M.D. EDIN.,

D.P.H. CANTAB.,

MEDICAL OFFICER OF HEALTH, LEICESTER.

SINCE I have been connected with the public health service I have always felt that there was room for improvement in the treatment of scarlet fever patients. It seemed to me that the long stage of desquamation, during the greater part of which the hospital patients are to all intents and purposes convalescent, was, to say the least, hard lines upon the general body of ratepayers, and that, therefore, all scientific endeavours should be directed towards the shortening of this desquamation period or towards the rendering of the desquamation itself in some way or other non-infectious. The average length of stay in hospital for scarlet fever cases varies in different institutions—e.g., in Leicester Borough Hospital it is about six weeks, as compared with seven to eight weeks or longer in the hospitals of the Asylums Board. Then, again, despite such a lengthened stay in hospital, patients when sent home appear (in a proportion of cases at least) to give rise to the disease in others. These are the so-called "return" cases—i.e., cases that are apparently, in some way or other, connected with the return of convalescents from infectious diseases hospitals to their homes; and their occurrence is disheartening when all possible precautions are taken in the way of keeping the patients isolated in hospital until every visible trace of peeling is gone and in the way of scientifically disinfecting clothes &c. As the result of my own investigations into "return" cases of scarlet fever, I have long felt that perhaps the desquamating stage is not their *vera causa*, the peeling skin not being so infectious as is generally supposed. It is true that

⁹ In fifteen cases of joint disease in inherited syphilis collected by Mr. J. Hutchinson, jun., one-sided knee affection is mentioned five times, but the time of observation is too short; and the clinical notes, especially in Virchow's cases, are too incomplete to allow these cases to be regarded as unilateral.

¹⁰ Hutchinson: *Syphilis*, p. 415.

¹¹ In this respect my case is in striking contrast to one published by G. Ogilvie (*THE LANCET*, June 10th, 1893), where syphilis could be traced from the "father" to all of the offspring. Out of nineteen confinements eight children survived, all showing to a greater or less extent the hereditary taint.

¹ A paper read before the Epidemiological Society, March 15th, 1895.

⁷ Syphilis, p. 76.

⁸ Mansell Moullin also in his *Surgery*, London, 1891, p. 97, says: "Interstitial keratitis always attacks both eyes." This is only approximately correct for the cases due to congenital syphilis; it does not hold good for interstitial keratitis in acquired syphilis, which is as a rule unilateral.

we as health officers are satisfied if we discover an antecedent case of peeling in the neighbourhood of a localised outbreak of scarlet fever, but it is equally true that in Leicester, when at the time of the outbreak of small-pox not less than 120 children in various stages of desquamation after scarlet fever were sent to their homes, no single second case occurred at any of these houses, although I carefully watched them for three months. Surely this was not a pure coincidence? My own line of reasoning is as follows. Scarlet fever is an infectious disease due to the entrance into the system of a micro-organism—the micrococcus scarlatinae of Klein, the bacillus scarlatinae of Edington, or other germ—the point of attack being in all probability the throat. On entering the body at this point, and incubating there for a certain length of time, the poison (be it the germ or its products) gives rise to certain changes in the blood, with a resultant train of symptoms—e.g., temperature and rash, followed by peeling of the epidermis. The simplest explanation is that the rash—i.e., hyperæmia or congestion of the skin—causes its outermost layers to die, to be thereafter cast off as waste products. No definite, generally accepted specific germs have as yet been found in this shed skin, nor have any cultivations been made therefrom, as far as I know; indeed, such skin is dead, and it has therefore seemed to me a little difficult to understand how such dead skin could so readily give (as it is generally stated) rise to the disease in others. I do not, of course, definitely state that it does not, but it has not yet been satisfactorily proved that it does; whereas experience, I think, is tending to prove that scarlet fever is extremely infectious in its early stages—i.e., from the moment that sore-throat and vomiting appear. Small-pox is undoubtedly infectious in its very early stages, as are also measles, diphtheria, influenza, whooping-cough, and typhoid fever. The fever stage in scarlet fever lasts from a week to two weeks, and the stage of desquamation from six to seven weeks. Presumably, when the fever stage ends the germs and their products have ceased to act deleteriously, and theoretically, therefore, all that is required is to render aseptic during the fever stage the blood, secretions, mucous membranes and skin, breath, &c. This Mr. Curgenvin claims practically to have done—a claim not yet seriously contested; and when my attention was first called to his eucalyptus treatment I may, perhaps, be described as being almost prejudiced in favour of such a line of treatment or disinfection. I read all Mr. Curgenvin's papers, and even after allowing a deduction for the praises naturally lavishly bestowed by a father upon his own offspring I felt that I had at last found my long-looked-for and long-wished-for remedy, by means of which I should be able to save my authority a considerable sum of money, whilst at the same time a much larger number of patients suffering from scarlet fever could be treated in my present hospital accommodation per year. Considering that Mr. Curgenvin unfortunately had to base his conclusions in regard to scarlet fever upon twenty-six cases, I anxiously waited for further statistics from other medical men, but none came. I decided, therefore, and through the courtesy of my committee was enabled, to try the treatment at the Leicester Borough Hospital, seeing and treating all the cases myself. In fact, I was able as medical superintendent to treat the cases, and then as medical officer of health to watch that no evil results arose therefrom in regard to the spread of the disease in the town. I propose now to bring forward all my facts, so that each one may draw his own deductions therefrom, contenting myself with stating that the comparatively few cases (120) that have been treated with eucalyptus by me do not warrant any very definite conclusions being drawn, but may perhaps tone down somewhat the exaggerated statements of others (on both sides) and be an incentive to those who have opportunities to do so to officially give this treatment a trial and to publish careful notes. I personally feel, as no doubt others do, that the subject is one that ought to be stringently and scientifically criticised and a definite opinion "for" or "against" come to. Mr. Curgenvin's paper, having the honour of being printed in the Transactions of the Epidemiological Society, and therefore practically "passed" by the society, holds the field, and his conclusions, until rebutted, must be accepted.

I have carefully followed out the treatment as suggested, personally supervising it, and have only included amongst my cases those patients who showed the rash well developed, so that not only was the diagnosis certain, but the disease had not advanced beyond its early stages—i.e., first or second day. It would be manifestly unfair to include cases with only initial symptoms—e.g., sickness, headache, and

sore-throat,—as whatever the result of the treatment might be in such patients it could never be definitely stated that they were genuine cases of scarlet fever, for I confess that I am one of those who deny the existence of scarlet fever without rash and subsequent peeling (branny or otherwise), though I recognise the so-called pseudo-scarlatinal cases, which are sometimes met with in scarlet fever infected houses or in times of epidemics, but which are not, in my opinion, genuine cases of scarlet fever. My mode of treatment has been as follows:—Careful rubbings with the oil over the whole body three times a day for three days, followed by one rubbing (after a warm bath) daily for seven days. The disinfectant is sprayed also into the patient's throat, mouth, and nose, and diffused into the air of the room. No eucalyptus has been administered internally beyond what passed down into the stomach during the spraying process. Further, sequelæ and complications as they arose were treated with the usual remedies—in addition, of course, to the eucalyptus oil. The oil that I use is Tucker's oleusaban "A" disinfectant, which is stated to be the essential oil of eucalyptus globulus with thymol and other camphors and aromatic antiseptics in solution in definite proportions, freed from most, if not all, resins and aldehydes by distillation and redistillation. There is stated to be a fluid hydrocarbon (eucalyptene) holding in solution an oxidised hydrocarbon isomeric with camphor—viz., eucalyptol. The eucalyptus oil is volatile and diffusible, evaporating readily, and so offers little or no obstruction to the pores of the skin, and it does not turn rancid. It is stated further to contain no fixed oil, no water, and no alcohol, and to be a non-poisonous, non-staining, and non-irritating germicide, antiseptic, and antiferment, according to the researches of Omelchenko, Bucholtz, Siegen, Mayo Robson, Lister, Schultz, Klein, Pitzer, Hirst, and others. I have compared the 120 patients treated with eucalyptus with 161 treated in the usual orthodox way, and at the same time, in the same hospital, and under precisely the same conditions—i.e., I have only included cases that showed the rash well out and were in the early stages of the disease. Further, all my patients were taken from the same epidemic (a declining one) and in rotation as they were notified, so that no selection of cases took place. In short, as far as possible, I chose my two sets of cases so that they practically agreed as to age, constitution, conditions of life, stage of disease, and severity of attack, the only difference, therefore, being one of treatment—i.e., eucalyptus v. orthodox or ordinary. The total 281 cases were the only suitable ones admitted to hospital during 1894. The majority of the cases were of a mild type. My results may be tabulated as follows:—

Details of cases.	Eucalyptus.	Ordinary.
Number of cases of scarlet fever treated and number of deaths ...	120 cases and 2 deaths. Per cent. 1·6	161 cases and 7 deaths. Per cent. 4·3
Length of stay (in days) in hospital—		
Non-fatal cases... ..	34·4	42·7
Fatal cases... ..	8·5	13·4
Length of interval (in days) between admission—i.e., commencement of the treatment—and normal temperature—i.e., the cessation of all fever... ..	11·4	10·3
Percentage of complications and sequelæ	20·0	27·3
Serious	79·3	83
Trivial	20·7	17
Percentage of "return" cases—i.e., of all those treated with eucalyptus and discharged from hospital during 1894	3·9	5·0
Calculated on special cases treated ...	4·2	6·4
Particulars as to Complications and Sequelæ.		
1. Serious—	Cases.	Cases.
Rhino-rhœa	2	7
Otitis	9	4
Phagedæna pharyngis	2	4
Acute rheumatism	2	1
Abscesses	12	14
Albuminuria	10	3
Uremic convulsions	1	4
Pneumonia	1	2
Acute tuberculosis	1	1
Hæmaturia	0	1
Meningitis	0	2
Anasarca	0	
2. Trivial—		
Tonsillitis	2	2
Pityriasis	1	0
Urticaria	1	3
Epistaxis	0	1
Erysipelas	0	1
Reinfection—i.e., secondary rash	2	3

It must be stated that with twenty-three exceptions the eucalyptus cases were kept in hospital until their skins were quite smooth—i.e., until all visible peeling was gone. If we take the 97 cases that were thus kept in hospital until all peeling was finished, we find the average stay in hospital of each patient was 35.6 days, whilst the average stay for the 23 patients who were sent out still peeling on the feet was 32.4. It makes, therefore, little difference, so that we may treat of all the eucalyptus cases together, with the understanding that practically each case was detained in hospital until the skin was smooth. I do not feel justified in sending the patients out into the town at the end of ten days as suggested by Mr. Curgenven. As medical officer of health I feel chary of doing so, of being a party to such an arrangement; though as medical superintendent I sent 23 patients out with peeling feet (the rest of the body being smooth) without any bad results accruing—without, in short, coming into collision with my other self, the medical officer of health! The 5 "return" cases in connexion with eucalyptus patients have reference to those who were perfectly smooth, all peeling having ceased, though I may mention that 2 were connected with patients who were discharged (at the request of the parents) with running ears; and we must all admit that a suppurating middle ear is theoretically an ideal cultivation medium for germs, and practically has been shown to be so by the interesting bacteriological investigations of Dr. F. Blaxall, who shows that the streptococcus pyogenes, and the staphylococcus albus and aureus are constantly found there, whilst Frankel's diplococcus pneumoniae and Friedländer's bacillus pneumoniae have also been found by other observers. Of the 5 "return" cases, the patients in connexion with whom they had apparently arisen had been 35, 23, 25, 44, and 34 days respectively in hospital, whilst the intervals elapsing between the dates on which they returned home and the "return" cases sickened were 5, 15, 6, 8, and 12 days respectively. Taking my own eucalyptus statistics, then, it would appear that there were in those particular cases in favour of the eucalyptus: (1) a lower death-rate; (2) a shorter stay in hospital; (3) slightly fewer complications of a serious nature; and (4) fewer "return" cases; whilst the process of desquamation was certainly hastened with, I may add, a slightly increased epithelial loss. The stage of fever was practically the same in both sets of cases—if anything, slightly increased in the eucalyptus ones; and I would mention here that the fever was not supposed to be gone until normal temperature had been not only attained, but also maintained. Two doubtful cases of scarlet fever out of 5 that were put into the eucalyptus ward and treated developed a rash, sore-throat, and temperature in 4 and 9 days respectively. Other results noticed were stimulation of the skin with feeling of warmth to patient, brightening of the colour of the rash, slight cough, slight suffusion of conjunctivæ, and tendency to sleep after the application, pulse softer and less rapid, whilst the smell of the oil was but slightly objected to. As to the cost of the treatment, my figures work out to about 2s. per patient, and taking the average number of rubbings as sixteen it is equal to 1½d. to 2d. per application (about an ounce being used each time). The stay in hospital, however, is shorter, and so the hospital maintenance expenses per patient are less. In Leicester during the last nine years the average weekly cost per patient is 16s. 2½d., and this I take in connexion with an average stay in hospital of 42.7 days for orthodox, as against 34.4 for eucalyptus, treated cases. There is thus a saving of a week's expenses—i.e., 16s. 2½d., whilst the oil costs 2s., leaving a balance of 14s. 2½d. in favour of each patient treated with eucalyptus, even when such patient is kept in hospital until smooth.

[Dr. Priestley then quoted from the reports of others. Thus Mr. C. Knox Bond, resident superintendent at the Liverpool City Fever Hospital, published in THE LANCET of June 6th, 1891, that during 1890, 305 cases were admitted, and 47 (44 consecutive cases) were treated with eucalyptus, but not by inunction. The oil was administered internally and the throat sprayed. The mortality was 8.5 and the complications 42.5 per cent. Mr. H. G. Armstrong, medical officer to Wellington College, read a paper on June 27th, 1894, before the Medical Officers of Schools Association. He had not tried the treatment himself, but had asked other medical officers of schools and superintendents of metropolitan fever hospitals. Of twenty-three medical men who were asked—Does antiseptic inunction prevent infection?—nine said "yes" or

"probably," three said "no," two were doubtful, and nine had no experience. In answer to the question—Does the inunction shorten the disease or prevent complications?—seventeen said "no," four said "yes," and two expressed no opinion. The conclusions drawn by Mr. Armstrong, who somewhat ridiculed the treatment by calling it the "bacon fat method," comparing it with a method adopted at Hanover, were—(1) antiseptic inunction does not exert any specific power over infectious diseases; and (2) it has but little if any power in preventing the spread of infection. Mr. R. M. Bruce of the Western Fever Hospital treated 16 cases by antiseptic inunction; 5 cases were uncomplicated (equal to 31.2 per cent.), 11 cases showed complications (68.8 per cent.), and 1 case died (6.25 per cent.). Mr. Curgenven quoted statistics of a fever hospital of 16 cases in which 30 per cent. had suppurative complications and 1 case died from "lung disease." Dr. Sweeting, late of the Western Hospital, says "the advocacy of the eucalyptus treatment rests on a crude generalisation." Dr. Edward Little of Wimbledon reported favourably on the treatment. Dr. Thresh of Chelmsford reported (from his own experience and that of others) unfavourably. Mr. Peake of Shepherd's-bush and others supported Mr. Curgenven. Drawing a comparison between hospital and home nursing Dr. Priestley said that in Leicester during the ten years 1883-92 7612 cases of scarlet fever were notified: 4488 were treated in hospital, where the death-rate was 3.6 per cent.; 3124 were treated at home, where the death-rate was 8.2 per cent.]

In conclusion it will be understood that my only desire is to get at the truth of this eucalyptus treatment and to inspire my colleagues to scientifically investigate it, at least in regard to scarlet fever. There is, I think, more in it than the "bacon fat" of Mr. Armstrong, though less than the "hospitals disestablishment" of Mr. Curgenven. *In medio tutissimus ibis.*

Leicester.

CASES ILLUSTRATING THE SURGERY OF THE KIDNEY.

By J. KNOWSLEY THORNTON, M.B., C.M. EDIN.,

CONSULTING SURGEON TO THE SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN, AND TO THE NEW HOSPITAL FOR WOMEN, AND THE GROSVENOR HOSPITAL FOR WOMEN.

(Continued from p. 698.)

JUST after correcting the proof of my last paper I was asked to see the patient described under Case 39 in consultation, and found that she had in some respects relapsed into the condition before the removal of the kidney. The urine is quite as bad as it has ever been—viz., bloody, pyoid, and extremely offensive—and the warty condition of the vagina has returned, though it is not as bad as before. There is no sign of inflammation or suppuration in the tissues of the loin above and around the ureteral stump, and the latter is to be felt quite distinctly as a small and very tender swelling about the size and shape of a large almond. There is no fever and the pulse is quiet and of good character. The patient takes her food fairly well, being not nearly so emaciated as she has been, and can get out and about when allowed to do so. It is, however, the getting up and getting about that reproduces all the mischief. When she is kept at perfect rest in bed, and has the bladder carefully washed out frequently with antiseptics, the urine gradually clears and becomes in time bright, acid, and normal, and the vaginal trouble also subsides. Then if she is allowed to get up almost immediately slight bleeding occurs at the end of micturition, and in a few days the urine is again in its old foul condition. Evidently the least movement sets up hæmorrhage, and then putrid suppuration in the little sac in which the stones lie. It seems clear that another operation will be necessary to remove the stump of the ureter and the calculi, and I believe the best way of reaching them will be by turning aside the peritoneum and its contents, a modification of Abernethy's operation for ligaturing the iliac artery. The chief risk of the operation lies in the probable adhesion of the parts to the peritoneum and the possible adhesion to the iliac vessels, as they are lying very near the point at which the ureter crosses them. The only alternative is a very prolonged rest in bed, but I do not feel at all confident, or even hopeful, that there

would not be a relapse when she got up again. Case 19 seemed to demonstrate that it was a safe practice to remove a damaged kidney above an impacted stone, and leave the latter alone when its situation rendered its removal specially dangerous; but Case 39 shows that one cannot depend upon such a satisfactory result, at any rate when more than one calculus lies in the ureter with a space between them. I shall still hope at some future time to record a successful ending as regards that case.

CASE 40.—A man aged forty-eight consulted me in the summer of 1892 about a large tumour in his loin, which had been slowly growing for some time without causing him much trouble, but latterly had begun to be a source of discomfort when jolting about on an Irish car, his duties giving him a great deal of such travelling. I diagnosed renal sarcoma and advised its removal, and the operation was performed on Oct. 11th, 1892. There was nothing calling for special comment in the operation; it was a large tumour, and a good deal of care was required in its enucleation in order to avoid serious loss of blood. I fastened the ureter into the lower angle of the abdominal incision and drained the sac with a glass tube. For twenty-four hours the patient was very well; then he began to hiccup, and this gradually increased in violence till I could hear him when I entered the hall of the house, though he was in a top back room up three flights of stairs. Nothing in the way of drugs had the smallest effect upon it, and I was seriously afraid that it would kill him, for it was incessant, shaking the bed and, indeed, the room; and though he was naturally a very strong man I felt that he could not stand it much longer, when, at the end of forty-eight hours, it ceased as suddenly as it began and he made a speedy recovery. The urine before the operation contained about a third of albumen and was of rather low specific gravity, and the sediment was full of blood corpuscles, renal cells, and much granular debris. It became quite normal soon after the operation. The tumour had evidently started in the capsule, gradually invading the substance of the kidney, and at the date of operation was invading the pelvis. The specimen was unfortunately destroyed without microscopic examination. The patient was very soon able to resume his work and when I last heard from him was in excellent health and spirits, finding no inconvenience from jolting about the country.

CASE 41.—This was also that of a male patient, aged twenty-nine, who was seen in consultation with Dr. Anderson in November, 1892. He had long been aware of the presence of a large tumour in his left side, and had at times suffered attacks of pain, which were so severe as to cause him to roll on the floor in agony. He had consulted many of the leading physicians in London and on the Continent, and all had told him that he was suffering from tumour of the spleen and that operation was out of the question. Knowing Dr. Anderson's special experience in such cases he sought his advice and was at once told that it was not an enlarged spleen at all, but an enlarged kidney—probably a case of hydronephrosis—and in this view Sir William Broadbent and I concurred, and it was decided that I should remove it. The operation was performed on Nov. 19th, 1892, and was without any special complication, and he made a perfectly smooth recovery, except that after I ceased to attend him he had a very alarming attack of severe internal pain and collapse, the exact nature of which was not very clear, and it was quickly recovered from. He was travelling and shooting in Egypt within six months, and has since been able thoroughly to enjoy life, playing cricket, shooting, and, in fact, doing everything that any other healthy young man of his age can do. The exact pathology of the case was somewhat obscure, but the ureter was practically obliterated, and I am much inclined to think from his history that it may have been a congenital one.

CASE 42.—The patient, a woman aged thirty-two, was sent to me by Mr. Tivy of Clifton in January, 1893, with a large abdominal tumour, evidently cystic, and I added to my notes "probably hydronephrosis." I advised operation and removed it on Jan. 14th, 1893, ligaturing and dropping the cut end of the ureter, which was like a very minute cord, but evidently pervious. This again was a case of inadequate ureter. The convalescence was rapid, and she is now in excellent health. A carefully kept record of the amount of urine passed showed a distinct drop in quantity on the third, fourth, fifth, and sixth days, then a return to the normal quantity for a few days, and then a very decided polyuria lasting for five days. This seems to be the natural course in a well-doing case.

CASE 43.—A man aged thirty-four was sent to me by Dr. Seton, who had diagnosed suppurating hydronephrosis. When a lad aged seventeen the patient had received a kick in the abdomen at football, passing blood in his urine for fully two years, and some swelling was observed at the time in the left side of the abdomen. On two subsequent occasions, after severe exercise, he suffered from attacks of pain with sensation of swelling in the left side, both attacks slowly passing off in three or four weeks. In 1879 he got a chill during a night march in Afghanistan and was said to have cystitis; the urine became cloudy and had remained so ever since. On his return home in 1880 Sir Henry Thompson examined him and said there was nothing wrong with his bladder. In the following year he consulted a distinguished physician, who said that there was nothing wrong with his kidneys and from his prescriptions evidently considered it to be a case of chronic cystitis. The ache and swelling in the left side of the abdomen had returned about a dozen times since the first attack, and on each occasion he had lost colour and flesh. In 1891 he began to suffer from general malaise and could not bear exertion; lifting a can of water or climbing over a gate would upset him entirely. I found a large, hard, fixed swelling in the left side of the abdomen, which I had no doubt was a suppurating kidney and I advised its removal. I operated on March 23rd, 1893. The ureter was found to be exceedingly small and entered the kidney at some considerable distance from the vessels; it was tied and sutured into the lower angle of the abdominal incision. I placed a rubber drainage-tube in the sac, and there was a very considerable discharge of bloody serum through it for some days after the operation. The kidney contained a pint and a half of offensive pyoid urine and weighed, after removal of this fluid, 1 lb. 9½ oz. He was very much troubled during convalescence with a bad cough, this leading to a good deal of irritation about the drainage-tube, and there was some brawny swelling in the loin for some time after he had begun to go about, but it gradually cleared up, and when I last heard of him he was in excellent health. The prolonged passage of blood in the urine after the kick is a curious feature in this case. The attacks of pain were probably at first due to distension of the pelvis with urine, and this caused hydronephrosis, which became pyonephrosis after the chill in Afghanistan. The peculiar attachment of the ureter to the kidney and its small size would greatly facilitate the various pathological changes following the kick. The quantity of urine passed from the bladder did not become normal in this case till nearly two months after the operation; the polyuria commenced on the seventh day and reached its height on the twelfth day.

CASE 44.—The patient was a single woman aged forty-four, who was in the habit of travelling a great deal and had very shortly before she saw me been travelling in little frequented regions, where she was much on horseback and driving in rough conveyances over rough roads; she was happily unconscious that she had any serious illness, though she had a very large suppurating kidney. She was so unconscious of its doing her any harm that I had considerable difficulty in persuading her that an operation was necessary. Some pain along the edge of the ribs in the left side and a catch in her side on stepping out of a railway carriage had led her to seek the advice of Dr. Knowling, who sent her to me. She had a tuberculous history on the mother's side and had had a sharp attack of right pleurisy a few years before the present illness. In February, 1893, she suffered from influenza and during its course was seized with shivering sickness and pain in the left side and had a tender swelling in the left side of the abdomen and pus in the urine, but she got better and thought no more about it till the occurrence of the symptoms named above. I operated on June 1st, 1893, and removed a large tuberculous kidney with a much thickened ureter, the stump of which I fastened out in the lower angle of the abdominal incision. She made a very quick recovery, with the exception of some little irritation about the end of the ureter. I had noticed this in other tuberculous cases, in one of which there was some ulceration, and I feared that there was going to be some serious breaking down of the wound, but a free application of tincture of iodine stopped it. Whenever I think that the ureter is sufficiently patent I am in the habit of letting a little tincture of iodine run down it into the bladder each time I dress the wound; it hastens the drying up of the ureter and keeps the urine sweet just at the time when it is liable to become contaminated by pus flowing into it from the ureteral stump. The patient remains well.

CASE 45.—This was that of a young woman sent to me by Dr. E. R. Butler. It was a left hydronephrosis containing five pints of urinous fluid. There was nothing of special interest in the operation or recovery, hence a description of them is unnecessary. The patient is now in very good health.

CASE 46.—This was a very interesting one. The patient, a young woman aged thirty-four, had always been strong and healthy till 1891, when she suffered much from constipation and from frequent calls to micturition, which always left her with a feeling that she had not emptied the bladder. She consulted Dr. Little of Dublin, and under his care improved, and he did not hear of her again till he was asked to see her in consultation and found that she had been under the care of Dr. Macan, who after the failure of a course of vesical injections had opened and drained the right kidney through the loin. Before this operation she had rigors, high fever, and much pus in the urine; the latter was seen by the endoscope to be flowing from the right ureter. In December, 1893, she called on Dr. Little on account of a discharging sinus in her side, complaining of pain in the rectum and in the meatus, which always came on about 11 A.M. Action of the bowels and passing urine would sometimes relieve her, but not always. After being in bed some hours at night she would have a free flow of urine, and then was better till the next day. Mr. Ball removed a mass of hæmorrhoidal tissue from the rectum, which gave relief while she remained in bed, but as soon as she was up again all her troubles returned, and Dr. Little sent her to me. I found a sinus over the right kidney from which offensive pus was oozing, and she said that a little urine sometimes escaped also, but that there had been very little pus in the bladder urine since the operation. The evidence as to the presence of tubercle was conflicting. One expert said he had found the tubercle bacilli, another could find none. The kidney was very fixed, and I explained to the patient that the operation of removal of the kidney would be a specially difficult and dangerous one in preference of this fetid sinus, but she said her life was so miserable that she would face anything to get better. I operated on March 29th, 1894, and with much difficulty encircled the kidney, the adhesions being very dense and running along the spine and great vessels. I began by carefully cleaning out the sinus and washing out the kidney with strong iodine solution, and during the operation I was very careful to avoid fouling the sac; immediately the kidney was out I flushed the sac well out through the sinus with a 1 in 1000 corrosive sublimate lotion. My precautions were successful, for she had no fever after the operation, and practically no discharge from the sac, which I drained with a glass tube in front and a rubber one through the loin sinus. The ureter was not thickened and enlarged, as is usual with tubercle. I pinned it into the lower angle of the wound, and had no further trouble with it. Convalescence was very satisfactory and rapid until she was up and about, when there was some return of bladder discomfort; but this soon passed off, and when I last heard from her she was in excellent health.

Remarks.—It is curious how constantly renal cases are subjected to bladder treatment, and yet it is not difficult in most of them to elicit facts from the patient which should, at any rate, make one suspect a renal origin, whereupon a careful examination will reveal some renal abnormality, and the more severely the bladder is left alone the better for the patient. Tinkering the bladder is a very dangerous business in face of a ureter discharging pus. Many a patient has told me that all the symptoms became serious after the simple passage of a sound into the bladder, and how much greater the risk must be when washings out and dilatations and digital explorations are practiced may be imagined. Mischief spreads up the ureter with great difficulty when there is a constant flow of healthy acid urine down it, but when this urine is mixed with pus or blood, or both, it is a very different matter.

(To be continued.)

FOOTBALL CASUALTIES.—On Saturday last, during a match between the Derby County Reserve and Stoke Swifts teams, a player received a kick in the abdomen and was carried off the field to the pavilion, but the extent of his injuries was not fully ascertained.—On the same day, in a match between the Royal Military College and United Services teams at Sandhurst, one of the home three-quarters was "kicked on the head in stopping a rush." He was seen by two medical men who were present and was then taken to the College Hospital.

ON THE ASSURANCE OF IMPAIRED LIVES, CHIEFLY WITH REFERENCE TO SPECIAL FORMS OF ASSURANCE.¹

By R. HINGSTON FOX, M.D. BRUX.,

MEDICAL OFFICER TO THE UNITED KINGDOM TEMPERANCE AND GENERAL PROVIDENT INSTITUTION, AND PHYSICIAN (FOR LONDON) TO THE FRIENDS' PROVIDENT INSTITUTION.

AN impaired life is a life of which we have evidence showing that the risk exceeds that of average lives, yet not so much as to render it uninsurable. The evidence is derived from: 1. Family history: this may show chiefly two things—(a) prevalence of some disease, especially tuberculosis or gout—inherited taint; and (b) a tendency to die early—a "breaking-down age." 2. Personal history: facts indicating (a) attacks of disease, especially lung disease, rheumatism, gout, heart disease, or epilepsy; and (b) showing general weak health. 3. The present condition is much the most important factor: (a) habits and occupation; evidence of intemperance of any kind, insufficient fresh air and exercise, exposure to chill, malaria, &c.; also various unhealthy occupations; (b) development and nutrition, including defect or excess of weight, ill-developed lungs, and premature age; (c) damage to organs and tissues, including the blood, lungs, &c.; and (d) disordered functions, circulatory, urinary, nervous, &c. In most cases evidence from several of these classes will be combined.

How far is it possible to classify impaired lives? Three categories are suggested:—1. Lives in which increased risk is attached to the early part of the expectation period, with a probability that if that be surmounted the expectation will be lived out or exceeded. The typical example of this is the young life in good personal condition, but with a tuberculous family history. It is matter of common clinical observation that the liability to phthisis falls especially on the early years of adult life. The Registrar-General's returns are sometimes quoted to show that such mortality is nearly as great in later life. This is true in the strict sense—i.e., taking the ratio of deaths to persons living at those ages; but if for insurance purposes we take 1000 persons living at the age of twenty-one we find of course that the number surviving to subsequent ages is constantly diminishing. The mortality calculated on these diminishing numbers will show a more marked decrease in later years:—

Age.	Registrar-General. Deaths from phthisis per mille per annum— males.	Healthy males. 1000 entering at age 21; numbers surviving (approximate).	Estimated deaths from phthisis per mille per annum of males entering at age 21.
20-24 yrs.	3.09	1000	3.09
25-34 "	3.70	937	3.46
35-44 "	4.12	855	3.52
45-54 "	3.86	752	2.90
55-64 "	3.19	600	1.91

These figures refer of course to all forms of phthisis. But Dr. Reginald Thompson has shown² that the mortality from inherited phthisis falls more markedly on early life than that from acquired phthisis, which is distributed throughout life. Hence the death-rate given above would show a greater decrease in the latter decades if deaths with a tuberculous family history were alone included. Further, the mortality from all causes greatly increases in later life, so that the proportion of phthisical deaths to total deaths will become less and less, ranging from 42 per cent. of all deaths at the ages 20-24, down to only 5.5 per cent. at the ages 55-64. That the risk in many cases of tuberculous inheritance attaches only to the earlier years of life may be illustrated by the history of two families: (a) consisting of seventeen children, of whom ten died, nearly all from phthisis, at ages 1, 16, 16, 20, 20, near 30, 32, about 36, 38, and 43 years, one from cancer at 57 (a daughter), and the remaining six lived on

¹ Introduction to a discussion by the Life Assurance Medical Officers Association, March 27th, 1895.

² Family Phthisis.

to 68, 69, 70, 79, 83, and 91 years, of generally delicate health, but long-lived; (b) the daughter just mentioned as dying at 57 years married her cousin, who himself died at 69 from chronic lung trouble. They had thirteen children: three died under 1 year; five died, mostly from phthisis, at 6, 17, 26, 30, and 30 years; one from pneumonia at 39; and four are still living at ages 60 to 73 years. There are a few other conditions besides liability to phthisis which produce a similar increased risk. Diabetes has been known to attack several members of a family in young adult life. A more common liability is that to acute rheumatism, which is often associated with the susceptibility to the group of specific fevers—scarlet fever, diphtheria, and enteric fever. Certain families are especially liable to this entire group of diseases,³ and the increased risk of death therefrom falls chiefly on the earlier and middle decades of life. A family history showing an early "breaking-down age," irrespective of special disease, will also place a life in this category. To meet this kind of increased risk we need a form of policy which will especially guard the earlier part of the period of expectation of life. The risk is a diminishing one. 2. A second category contains lives showing special risk at the other end of the expectation period. The typical instance of this kind of risk is found in a life entering young with an inherited taint of gout. When gouty disorders have already shown themselves in a life entering in or after middle age the life belongs rather to the first category, the liability to death within a short course of years being, as Dr. Symes Thompson has recently shown,⁴ greater than is generally supposed. A family history showing some prevailing cause of death in old age—such as cancer—or a personal history of slight asthma or dyspepsia indicates increased risk near the end of the expectation period without material addition to the risk at earlier ages. I am inclined to place here also cases of slight albuminuria with low arterial tension. The characteristic of this category is an increasing risk. It will be noted that it is mainly the evidence of family history which places a life in the two categories first described. In some cases this evidence is of great and obvious importance, but the experience of the Scottish Under-Average Association of Insurance Companies has shown that lives rated up on account of family history have had a much less mortality than those rated up for defective personal health. In most cases there is, however, besides the bad family record, some element of personal weakness, and where, on the other hand, a proposer has every sign of robust health and good development, family history has small weight. 3. The third and largest category includes lives with some general impairment of vitality. This will increase the risk, no doubt, chiefly in the latter part of the expectation period, but also more or less during the whole of that period. The evidence of this impairment may be illustrated by the following: a generally unsatisfactory family history, showing various deaths in middle life; a personal history of weak health without special illness; a personal condition of poor nutrition, anemia, premature age, damage to organs, especially the heart; any cause that diminishes the resisting power of the body to disease influences; hence unhealthy habits and occupations. Taking these lives as a group, the increased risk is represented by a shortened expectation period, and the form of assurance must provide for this general increase of risk. Mr. Chisholm has devised a diagram to show graphically the risk of death at various periods for a life entering at twenty years: a curved line represents the normal death-rate for each year of life, and this can be varied to represent the increase of risk at any particular epoch.⁵ With regard to the special forms of assurance best adapted to meet these various risks, it may be objected that this is a question for the actuaries alone. Yet surely the medical officers of companies are constantly advising recourse to this or that form of policy. And whilst it is for the actuaries to devise forms of insurance to meet the special risks which we can define, and to work them out in detail on a sound financial basis, it is surely our part to understand that which they have devised, and to examine its applicability to the various risks with which we meet, so that our advice to the companies may be founded upon a full knowledge of the methods in use. Before going further allusion may be made to one guiding principle in the provision made for these risks—viz., that as a rule all weak lives should be subjected to some

kind of extra rate, whether in the event they prove to be under or over the average length. It is surely no injustice that an impaired life should be thus charged, even if that particular life reaches or exceeds its expectation. I mention this because the contrary has been maintained. An American actuary (Mr. Fouse) writes that the correct principle is only to treat "those lives as under average which prove themselves to be so."⁶ It is obvious that a very much heavier extra rate must be put upon impaired lives if it is only to come into force in the event of their falling in early.

I propose now to pass briefly in review the chief forms of assurance in use in this country, with special reference to their applicability to the risks of impaired lives: 1. The ordinary whole-life policy, with annual premium, about which it need only be said that it may fairly cover a considerable margin of risk. 2. The ordinary whole-life policy rated up in the manner usual in this country—i.e., by taking the life at an assumed age, say five, seven, or ten years in advance of the real. (The practice of making small advances of one, two, perhaps even three years, to meet slight extra risks is, I imagine, generally felt to be inexpedient.) This is a very convenient and straightforward method of dealing with increased risks, and no doubt in the main works very well. Investigations which have been made by various companies, such as the Eagle and the Equity and Law Companies, have, I believe, generally shown that the advances imposed have about or nearly met the extra mortality of impaired lives. This may not be true of certain classes of risks, particularly of gout, as shown by Dr. Symes Thompson and others, but it appears to be true of all the risks taken in the aggregate. This method of meeting increased risks has a somewhat unequal application to the different ages of life. Thus, in early adult life, when the premium rates are low and increase very slowly, an advance of seven or ten years results in a comparatively small addition, and the loss to the office if death occurs early in the expectation period is scarcely lessened. On the other hand, at or after middle age an advance of seven or ten years becomes almost prohibitive. It is important not to fix these advances by any mere "rule of thumb"; the use of the table of expectation of life affords a more scientific method, as one can form some idea of the shortening of the expectation period appropriate to the case, and then see to what advance in years this may correspond. A simple advance, then, treating the life as a little older than the real age, seems fairly to meet the third category of impaired lives, where there is a generally increased risk attaching to no special period. A typical condition is that of premature ageing. When the risk attaches to the earlier years, I submit that a form of advance which better protects the company against the risk should be adopted. And when the extra risk belongs to the latter part of the expectation, a form of advance more acceptable to the proposer can be found. The mortality experience collected by the Institute of Actuaries in 1869 showed clearly that after the first five years from entry the mortality of impaired lives accepted for insurance was but little greater than that of healthy lives. Thus, during the first five years the mortality of diseased lives at ages twenty-five to thirty-four was 62 per cent. higher than that of healthy lives, and at sixty-five to seventy-four 25 per cent. higher; but after the five years had expired the percentage of increase ranged from but 29 to 16 per cent. This suggests that the risk of lives accepted at advanced rates really falls, in no inconsiderable proportion of instances, upon the early years after assurance. 3. A policy subject to temporary deduction from the sum assured; otherwise, charging the policy with a diminishing lien or contingent debt. By this method, originally proposed by the late Mr. M. A. Black in 1861,⁷ and improved by Mr. W. M. Makeham in 1872,⁸ a deduction is made from the full value of the policy in the event of death occurring within a definite period, usually the expectation of life; a large deduction if the death occurs early, but gradually diminishing until the end of the period, when it vanishes, and the policy is paid in full. The amount is calculated to be equivalent in value to an advance of a given number of years. This method, which is explained and commended in Dr. Pollock's and Mr. Chisholm's handbook,⁹ is referred to by Dr. Reginald Thompson as peculiarly applicable to cases in which a phthisical family history is present, and it certainly seems to provide against a risk attached to the early years of adult

life in a more satisfactory manner than any other in use. Take the case of a man entering at twenty-one years, of good personal condition, but with a family history of phthisis fatal at early ages. It is but little protection to the company to advance his premium rate a few years. In the aggregate of impaired lives the company may not lose, but is not the balance maintained by making the lives of other and less urgent risk pay for his special risk? On the other hand, such a proposer may fairly be expected to submit to a deduction of this kind as the penalty of his particular risk.

[To illustrate this matter Dr. Fox showed a table and chart exhibiting the loss to the company attaching to death at various ages under several different forms of policy, from which it appeared that the only method which met the risk of the early years after assurance was the deduction policy. He continued:]

This is no doubt largely an actuarial question, yet it seems to me that as medical officers we might do well to represent to our actuarial colleagues that there is a special class of risk which needs such a method as this to meet it adequately. The method is in use by several companies, but does not seem to be as well known as it deserves. It will be observed that this method of dealing with impaired lives is not in accordance with the rule submitted just now, that the extra rate should be of a nature to apply to all such lives whether they die early or later. The plea, however, is that to meet a special limited risk the rate should fairly be applied in the manner shown, and that it would not be just to burden all who survive this special risk in early life and live, perhaps, to old age, as in the instances given, with a heavy charge. In advocating the use of this form of policy it is not suggested that lives with a phthisical taint should be accepted more freely than is at present the practice, but only that they should be subjected to the conditions described. 4. The limited payments policy, under which the entire premiums are paid up in a fixed term of years—say, ten or twenty. A large sum is accordingly received in the early part of the expectation period, and, if death occur prematurely, the loss is less than under the usual plan of spreading the premiums over the whole of life. This lessens the risk in the case of impaired lives, but it does not fully meet it, since the rates are calculated upon the experience of healthy—that is, average—lives. It is not, therefore, proper to use this form of assurance for lives of increased risk without making an addition, excepting in cases of a slight character, in which the lessening of the risk may be considered to bring it within the margin of average risks. It is in cases with increased risk of death in the middle part of the expectation period that the limited payment policy is most useful, but a small extra rate should be added. 5. The endowment policy. This is a very interesting form of policy, and one which enjoys a just and increasing popularity in this country. It is of importance in the present connexion since Dr. Glover Lyon has told us that it is largely used in the United States, as I understand, without extra rating, for the assurance of under-average lives; but, as with the limited payment policy, so here the rates are calculated on average lives, and it cannot, therefore, be right to use the endowment policy without extra rating for impaired lives taken as a class. The large premiums reduce, of course, as in the former case, the loss to the office in the event of early death, and an actually smaller advance is needed than with whole life policies; this should be given in the form of a percentage addition. The special feature of an endowment policy, the term of which is almost always well within the expectation period, is that it cuts off the end of that period. Hence, as Dr. Pollock has told us, it may be of the greatest use for lives without sufficient stamina to carry them into old age, and it may be so applied as to cut the insurance short at the breaking-down age. It is, in fact, especially useful for the case of an increasing extra risk herein contrasting with the deduction policy, which is strictly applicable to a decreasing risk (Makeham). For lives with a phthisical family history this method has, therefore, a very limited use, since it leaves the early years unprotected. A tendency to gout, on the other hand, is especially well met by an endowment policy, provided the proposer comes before us pretty early in life, and the term of the endowment is fixed so far within the expectation period as the probable shortening of the life may require. And I would suggest that slight degrees of albuminuria, with low blood tension, may be appropriately dealt with in this way. In such cases, if the personal condition is otherwise good, an extra rating does not seem needful. It is understood that the mortality experience of

endowment policies is very favourable, no doubt in part owing to an unconscious selection amongst proposers. The endowment policy is, then, especially applicable to impaired lives of the second category, and with an extra rating to those in the third category.

Finsbury-square, E.C.

IMPACTION OF ENORMOUS GALL-STONE IN THE LOWER PORTION OF THE ILEUM; INTESTINAL OBSTRUCTION; LAPAROTOMY; ENTEROTOMY; RECOVERY.

By W. C. EVERLEY TAYLOR, F.R.C.P. EDIN.,
SURGEON TO THE SCARBOROUGH HOSPITAL.

THIS case is of interest on account of the comparative rarity of intestinal obstruction being caused by gall-stone, the enormous size of the concretion, the prolonged period the patient was on the verge of complete obstruction, and the remarkable recovery after so severe an illness.

On April 3rd, 1894, a woman aged fifty-six years, residing about two miles from Scarborough, sent for Dr. Rust and myself. She gave my colleague a history of continuous vomiting for a period of thirty-six hours. She seemed very exhausted. There was no evidence of organic disease or error of diet to account for it. She stated that she had been in perfect health for thirteen years, never having needed medical attendance since 1880, when Dr. Taylor opened a very large abscess in the thigh. Predigested food was ordered and a hypodermic injection of a quarter of a grain of morphia, $\frac{1}{4}$ gr. For the next forty-eight hours the vomiting was nearly continuous and nourishment of any kind was only retained for a few minutes. On the 5th at 8 p.m. I saw her. She was not so collapsed as the continuous vomiting, now lasting two days, would have led one to expect. On making a careful examination of the abdomen a little below the apex of the ninth rib a rounded swelling, slightly movable and dull on percussion, was discovered. There was no evidence of hernia at any of the hernial openings. There was no evidence of disease in any organ, nor did the examination of the rectum reveal anything; flatus had been passed and a small motion. The next day the condition of vomiting remained; feeding by the mouth was stopped, and nutrient suppositories were ordered every four hours. A careful examination by Dr. Godfrey and myself failed to discover the rounded swelling detected on the previous day. For the next five days all food by the mouth was prohibited, and peptonised enemata and nutrient suppositories were administered. Only a little water was allowed by the mouth. While this line of treatment was pursued there was no retching or nausea, and flatus was passed every day. On April 14th deep palpation in the left iliac region gave a sensation of localised hardness and resistance over a limited area. Every day the patient said she felt flatus passing through the intestines, which was expelled, and at no time was the vomiting of a stercoraceous character. Water when given by the mouth was retained, but any other kind of fluid nourishment returned unchanged. The patient volunteered a statement that one night in December, 1893, she had great pain over the site of the gall-bladder, which had kept her awake, that Dr. Scarth had seen her, and had said she had gall-stone. She had forgotten all about this until now, although previously questioned on this matter. On April 17th Dr. Cuff saw her in consultation, and the question of the escape of a large gall-stone by ulceration from the gall-bladder into the intestine was suggested as an explanation of the symptoms. It was decided to wait and not operate until the symptoms of obstruction became more acute. During the next few days the pulse and the temperature were normal and a little peptonised milk was given by the mouth which was immediately vomited. On April 24th it was decided to remove the patient into Scarborough, as it was felt that the necessity for an abdominal section might arise at any time. She bore the journey well. On April 27th the vomiting became stercoraceous, the temperature rose to 100° F. and the pulse to 120, the abdomen became distended, and no flatus had been passed for thirty-six hours, so abdominal section was decided upon. A median incision was made. It was decided to

explore the small intestines from the cæcum upwards if nothing was found in the left iliac region, where the hardness had been felt on one occasion. The intestines were much distended and bulged into the wound; the hand passed to the left iliac region came upon a flaccid coil of intestine, and tracking this upwards a hard mass was felt in the gut. This was gently brought to the surface. The bowel was clamped above and below the mass, and sponges were packed around it. An incision was made in the long axis of the gut one inch in length, and the gall-stone extracted. The wound in the intestine was closed with silk Lembert sutures. The peritoneum was sutured with sterilised silk, and the abdominal wound with silkworm gut. The patient bore the operation well. The temperature rose at 10 P.M. to 100.4°, which was the highest recorded during the convalescence. Nothing whatever was given by the mouth for the first twenty-four hours, but a small quantity of peptonised milk was given per rectum. After this small quantities of peptonised milk and beef-jelly were allowed. An enema was given on May 2nd, and was followed by a copious loose motion, flatus having been passed naturally on April 30th. No pain at any time was complained of either in the intestines or in the wound. The progress of the case was uneventful. Fish was allowed on May 3rd, meat on the 12th, the bowels acting every other day with enemata. The patient was kept in bed for three weeks, by which time the wound was soundly healed. The stone weighed 1½ oz. It was 4½ in. in circumference and 2 in. in length, of ovoid shape, with smooth, rounded ends. The illustrations give a good idea of its size.

FIG 1.

Showing greatest length.

The remarkable features of the case are as follows: the absence of any pain approaching to gall-stone colic, save in the previous December, which was not severe enough to have left any marked impression on the patient's mind; the sudden onset of the severe vomiting; the rapid disappearance of the mass from the region of the gall-bladder; the fact that at no time till April 26th was the evidence of intestinal obstruction complete; that with so large a mass impacted so low down in the small intestine the patient was certain that flatus passed completely through the whole length of the bowels; and that, considering the fact that the patient was entirely dependent upon rectal feeding for twenty-four days and quite realised the gravity of her position, her strength was so well maintained. Mr. Lane¹ has published a case on similar lines with a successful result, and Mr. Bryant² a case where the stone had a diameter of 3½ in., the patient dying. Calculi impacted in the bowels have

attained considerable dimensions. Mr. E. Pye-Smith³ records a stone measuring 4½ in. by 2½ in. lodged in the upper part of the jejunum. A stone 2 in. in length with a circumference 4 in. also in the jejunum has been noted.⁴ Of thirty-two cases collected by Leichtenstern in seventeen the stone was impacted in the lower ileum. Dr. Sands⁵ records a case where a stone with a diameter of 3 in. was passed at the end of five weeks, the stercoraceous vomiting lasting three weeks. The largest stone I can find any record of is Richter's case mentioned in Mr. Hutchinson's *Archives of Surgery* for July, 1891, where a stone weighing 3 oz. and 50 drachms was found post mortem. I cannot find any record of any gall-stone so large as in the case I am reporting having been removed during life. There can be no question that this calculus entered the duodenum by ulceration direct from the gall-bladder, and Mr. Treves says: "It will be evident that there need be no evidence of hepatic colic in a given instance if it be true that the stone usually reaches the duodenum by ulceration from the gall-bladder." Mr. Hutchinson says: "To turn to the class of cases in which real obstruction is present we may ask the question, Is it possible to make the diagnosis of a case where the small intestine is plugged by a gall-stone? I maintain it is not practicable to get further than a mere conjecture. If the case is recent it will count as one of acute intestinal obstruction, and a band or a twist or some other form of internal strangulation will be suspected. A differential diagnosis is simply impossible, for the symptoms are the same. There is little to help us excepting the history of an

FIG. 2.

Showing greatest depth.

early stage of symptoms referable to the region of the gall-bladder, and this is in many instances—I think in the majority—wholly wanting; cases of block by hardened faeces and by a malignant stricture may each in turn resemble it." It is, as a rule, impossible to diagnose obstruction from gall-stones from other conditions causing acute intestinal obstruction; therefore the surgeon should always bear gall-stones in mind when called upon to treat acute obstruction. I have sent the gall-stone to the Museum of the Royal College of Surgeons of England.

CASE OF RESECTION OF INTESTINE, WITH APPROXIMATION OF THE DIVIDED ENDS BY MEANS OF MURPHY'S BUTTON.

By J. PAUL BUSH, M.R.C.S. ENG., L.S.A.,
SURGEON TO THE BRISTOL ROYAL INFIRMARY.

I THINK this case may be of interest, as I believe it was the first occasion on which the Murphy button was used successfully in this district.

The patient, aged fifty-five, though a much older man for his age, and who had suffered all his life from a marked angular curvature of the spine and chronic bronchitis, came under my care for a strangulated inguinal hernia on Nov. 27th, 1894. He had had a reducible hernia for twenty years and had always worn a truss. Three days before his admission the hernia came down, and all the symptoms of an acutely strangulated hernia followed; he was treated, before seeing me, with an ice-bag and a turpentine enema, and taxis was tried, but without any reduction of the strangulated intestine. On his admission the patient was collapsed, there was stercoraceous vomiting, and all the physical signs and symptoms of a strangulated hernia were present; there was some fullness in the right iliac fossa with pain on pressure. Herniotomy was at once performed. On laying open the sac the smallest possible quantity of fluid was let out, and about four inches of small intestine were found to be so tightly strangulated that the hernia director could not be inserted until the constriction had been partly divided. The ring was then very freely divided and a small portion of the gut both above and below the constricted area was brought down for inspection. The strangulated portion was quite black, the surface glistening only in places; the upper end of the gangrenous portion appeared to be united to the non-strangulated portion of intestine by only the serous coat. A fresh incision about three inches long was made in the middle line of the abdomen midway between the umbilicus and pubes, and the strangulated portion of the gut was brought from the scrotal incision to the opening in the middle line. Swain's intestinal clamps were placed on the healthy intestine about ten inches apart, with the portion to be resected lying between; the gangrenous intestine was then resected with the scissors, about half an inch of non-strangulated gut on either side being removed with it. Some vessels in the mesentery were ligatured; no wedge-shaped portion of the mesentery was removed. The male and female portions of the button were fixed in the cut ends of the intestine by means of a purse-string of silk and the two parts of the button were fitted together; the largest size button that is made for the small intestine was used. No sutures were used to unite the divided intestine or mesentery. On removing the clamps the upper and distended intestine was observed to be emptying its contents through the button into the lower portion without a sign of any leakage; the gut was then dropped into the peritoneal cavity and the wound closed. As the patient was considerably collapsed before the operation commenced it was deemed advisable not to prolong the administration of the chloroform by performing an operation for the radical cure, so the scrotal sac was drained only, and the wound sutured. A little weak milk-and-brandy was given by the mouth during the night. On Nov. 28th the vomiting had ceased and the abdomen was somewhat distended. On the 29th the patient passed flatus frequently. On Dec. 1st there was considerable pain in the right iliac region and some distension. On the 2nd there was a slight action of the bowels. There was nothing special to record till the 4th, when there was a rigor, distension, and severe pain in the abdomen. The passage of flatus had almost ceased. There were dyspnoea and cough. The pulse was very weak and intermittent. Dr. Shaw kindly saw the man with me in the evening, and we decided that the grave condition of the patient was due to double pneumonia, and not to any complication of the intestinal lesion. Stimulants were freely given by the mouth, and a turpentine exema greatly relieved the distended abdomen. The patient from this time gradually improved. The bowels were opened twice on the 8th and 9th, and between the 10th and the 16th there was some diarrhoea. On the 14th a small quantity of blood was passed; no button could be felt in the rectum. On the 26th the patient was sitting up, and no button could be felt. On Jan. 4th, 1895,

Murphy's button was passed without pain. On April 2nd it was over four months since the operation; the man had been under close observation throughout, and there were no signs of any obstruction.

Remarks.—There are one or two special points I should like to notice. The advantages of the button are undoubted to my mind, as it certainly takes a very much shorter time to perform resection with the button than any suturing operation I know of, and this question of time is a most important one in intestinal surgery. It may be said that in dealing with small intestine cases, as the button must be small enough to pass through the ileo-caecal valve, the opening in the united ends of the intestine must be small also, and that the size of the ring tends to diminish. All I can say is that so far this case shows nothing of the kind. I have wondered whether a button could not be made with the expanded portions consisting of some such substance as decalcified bone, but retaining the ingenious ideas of Dr. Murphy in the spring screw arrangement of the male and female portions. If this could be done we should then be able to increase the size of the opening in the intestine very considerably for the small intestine cases. I think the making of a second incision in the middle line useful, as it is a much more convenient place to carry out the operation on the intestine, and it is a much less serious incision than that of opening up the inguinal canal for, say, three or four inches. Five weeks is a long time for the button to be retained, but then it must be remembered that its expulsion was not hastened in any way by aperients, as none were ordered till the morning of Jan. 4th. The patient, hearing the order given for a good dose of "house medicine," promptly got rid of the button before the dose could be administered.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

THE RADICAL TREATMENT OF LUPUS.

By RICHARD T. CESAR, M.R.C.S. ENG.

IN THE LANCET of July 21st, 1894, Mr. Bidwell published particulars of six cases of lupus treated by free excision and skin grafting, and in his paper he stated that he believed Mr. Watson Cheyne was the first to perform such an operation in this country, his cases being exhibited at the Medical Society of London in March, 1893. When Mr. Watson Cheyne performed his operations I do not know, but I should like to mention two cases in which I performed the very same operation, with the exception that I did not do the skin grafting. The first I performed nearly twenty years ago and the second about ten; in both cases I simply made a free deep incision all round the edges of the ulcer and raised the floor entire. I used no sutures nor in any way attempted to bring the edges of the wound together; I simply dressed it as an ordinary granulating surface, and both cases turned out all that could be desired without any return in either, and the resulting scar was trifling.

CASE 1.—A man aged sixty-two years consulted me in March, 1876, for an ulcer on the left side of his face, which he said had existed for some years, but of late was spreading very fast. He stated he had been under various treatment by different medical men, and had, as usual in such cases, tried all sorts of "certain cures" and quack remedies without the slightest good resulting. It was then so large and unsightly that he was compelled to give up his situation as coachman. On removing the dressing I found a patch of lupus much larger than a half-crown piece, situate on the left cheek and spreading towards the outer angle of the eye. I first tried the application of the usual remedies, but without benefit, and the man becoming impatient for some more active treatment, I suggested the complete removal of the diseased structure, hoping thus to make a permanent cure, and to this proposal he readily consented. With the kind assistance of my friend and former pupil, Dr. H. Payne, I made a deep incision all round the edges,

keeping well away from the diseased structures; I then dissected off the entire floor of the ulcer, keeping my knife well under the disease, so as to make sure of removing all the diseased tissues. Having applied pressure forceps to a few bleeding points, I dressed the wound with dry antiseptic dressing without strapping or sutures, allowing it to granulate; this it did most satisfactorily, and in a little time was well and the scar not particularly noticeable, so that he was able to resume his occupation. I had the advantage of constantly seeing this man for some years after, and there was no sign of the disease returning.

CASE 2.—A boy aged eight years was admitted into the Shirley Children's Hospital in December, 1884, with a large patch of lupus on the left cheek $2\frac{1}{2}$ in. by $1\frac{1}{2}$ in. He had been under treatment for some time, both private and hospital, before applying to me. I first tried local and general treatment, but as this failed to afford any prospect of cure, and the disease continued to spread, I decided to treat it after the same manner as the first case, and with the kind assistance of my colleagues, Dr. C. G. Beaumont and Mr. Chamberlain, I made a deep incision round the ulcer, keeping well away from all traces of the disease. This done, I dissected off the floor, as in the previous case, and treated it in every way the same, and the result was entirely satisfactory; the wound healed, and the resulting scar was not very perceptible. So far as I could afterwards learn, there was no return of the disease.

I do not publish these cases with any wish or intention of claiming priority for the operation, but to confirm Mr. Bidwell in the good results which he claims for the proceeding. No doubt the skin grafting may be of some advantage; but I do not think it is essential to the success of the operation, which I consider far preferable to the old plan of scraping, as there is more control over the diseased structures and a better chance of thoroughly removing them. Of course, the great point is to get well beyond the disease and not be afraid of removing too much; and, like all operations of the kind, the sooner it is done the better for the patient. Had I noticed the papers to which Mr. Bidwell refers I should have mentioned these cases before; but they must have escaped my attention, as I have no recollection of having seen them.

Wellington, Salop.

EPITHELIOMA OF THE TONGUE IN WOMEN.

By CHAUNCEY PUZEY, F.R.C.S. ENG.,
SURGEON, NORTHERN HOSPITAL, LIVERPOOL.

As a contribution to the statistics of epithelioma of the tongue attacking women¹ I send a short note of two cases upon which I operated in the summer of 1892. Curiously, both patients were admitted within a few weeks of each other, and they are the only cases occurring in women which have come under my care during twenty years of hospital work.

CASE 1.—The patient, a woman aged fifty-three years, had the left side of the tongue (posterior position) extensively affected with epithelioma, and several of the submaxillary glands of the same side were enlarged. She was in a very feeble condition from pain and starvation, but urgent in requesting operation. On June 20th, 1892, I removed the left lateral half of the tongue close to the hyoid bone. Very little blood was lost, but the patient was so weak that removal of the glands was deferred. For some hours after operation it seemed doubtful if she would rally; but after that she made a rapid recovery. A few weeks later the submaxillary region was thoroughly cleared out. For two or three months she improved remarkably, but then disease recurred in the glands at the back of the neck and the case soon ended fatally.

CASE 2.—The patient, a stout, ruddy, healthy-looking woman aged fifty-nine years, was admitted a few weeks later. She had a large epithelioma involving the middle portion of the right lateral half of the tongue and slightly invading the floor of the mouth, but without glandular enlargement. On July 29th, 1892, I removed the right lateral half of the tongue, close to the hyoid bone. She made a rapid recovery. Twelve months later I heard that everything was perfectly satisfactory, and so it continued until the end of last autumn, when disease recurred somewhere in the submaxillary region (I did not see her) and she died last Christmas. The operation had given her two years of comfort.

¹ Vide THE LANCET, March 2nd, 1895.

The operation in both cases was that generally known as Morrant Baker's, and the only other point to which I wish to refer is that there was throughout the whole period of the healing of the wound in both cases complete absence of fetor, which I attribute to the hourly painting of the whole wound with glycerine of borax.

Liverpool.

FAT EMBOLISM FOLLOWING FREE INCISION OF THE FEMALE BREAST FOR DIFFUSE SUPPURATION.

By SURGEON-MAJOR A. F. FERGUSON,
BOMBAY MEDICAL SERVICE.

THE patient, a healthy female twenty-two years of age, came to the Civil Hospital, Shikarpur, on April 7th, 1894, in great pain and looking very much worn out by intense suffering. The left breast was enormously swollen, red, and exquisitely tender, with a doughy elastic semi-fluctuant feeling uniformly throughout. The tenderness was so great that chloroform was necessary for examination. A free incision was made in what appeared to be the most likely situation. There was great hæmorrhage, but only a small quantity of pus. The excision was extended, but still no collection of pus was reached; the finger was introduced and passed through the gland, which was spleen-like in consistence, and the fingers could easily be pushed through it; but still only a small quantity of pus escaped, and it seemed to be equally distributed throughout the gland. A drainage-tube was inserted and a suitable dressing applied. The pain continued and the suffering seemed great. Morphine was given pretty freely, but she was very restless nevertheless. On the next day she looked extremely anxious and worn out, and the breathing was oppressed. The drainage-tube was removed, and some milky, oily-looking fluid escaped with it. There had been a good deal of bleeding, but only slight purulent discharge. The dyspnoea rapidly increased, and at 5 p.m. the following note was made: "The breathing is very much oppressed and 30 per minute, the face cyanosed, the pulse running, and patient unconscious." She died at 11 p.m. A post-mortem examination was obtained with great difficulty, and during its performance the relatives were outside clamouring for the body, so it was necessarily very superficial. The lungs were much congested, a great portion of the left approaching red hepatization. Portions were kept and hardened. The kidneys could not be obtained, nor could the other organs be carefully examined under the circumstances. Sections of the lungs, stained with perosmic acid and mounted in Farrant's solution, were shown at the Indian Medical Congress at Calcutta. They show the capillaries and smaller vessels blocked with fat, and globules of fat in the blood in the larger vessels.

UNIVERSITY COLLEGE HOSPITAL.

A CASE OF TUMOUR OF THE LUNG; REMARKS.

(Under the care of Dr. G. V. POORE.)

PULMONARY growths of a malignant character are usually secondary to disease in other parts. Probably in the large hospitals sarcoma of the lung secondary to bone disease of similar nature is most frequent, whilst in the infirmaries the disease is usually secondary to a scirrhous growth which first showed itself in the breast. This case is a most instructive one of primary sarcoma of the lung—a condition which, as this case demonstrates, is extremely difficult of diagnosis until evidence of compression of intra-thoracic veins or the appearance of tumours elsewhere affords additional aid.

Many cases which are recorded of primary growths of the lung are doubtful, for careful search does not appear to have been always made for a possible primary growth in other parts; here the examination was complete and conclusive. For the notes of this case we are indebted to Mr. A. M. Watta, house physician.

A man aged twenty was admitted to University College Hospital on Dec. 12th, 1894. He stated that on Oct. 8th of the same year he noticed, on getting up to go to his work in the morning, that he was very short of breath and felt cold all over. He had been quite well previously, but the symptoms were so severe that he took to his bed at once and sent for medical advice. He remained in bed till the end of the month, when, feeling better, he got up and went about for a fortnight, but did not resume his occupation. One morning about the middle of November, while out walking, he was suddenly seized with a severe aching pain in the middle of his back, which caused him to double up. He immediately returned home and took to his bed, stopping there till he entered the hospital. Since the middle of October he had suffered from pain in the left side, which was worse on coughing. For a week—a month before the date of his admission—he expectorated sputum stained with blood. He had been treated during his illness with poultices, blisters, &c. He had had influenza three years before, but no other illnesses. He said that he had always been delicate. There was nothing noteworthy in the family history. On his admission it was found that he had a slight cough, but no expectoration; he had some dyspnoea on exertion; there was no cyanosis; the respiration was 40 per minute. On examining the chest it was noticed to be poorly covered, long, and narrow, and that the intercostal spaces were better marked on the right side than on the left, which side hardly moved at all on respiration. Below the third rib on the left side there were absolute dullness on percussion and loss of vocal fremitus of breath sounds and of voice sounds. In the second left intercostal space there was distant bronchial breathing with egophony, the percussion note being impaired very much. In the first left intercostal space the percussion note and breath sounds were normal. Behind there were on the left side, below the spine of the scapula, very diminished vocal fremitus and dullness on percussion, with faint bronchial breathing and very weak voice sounds. In the left supra-spinal fossa the percussion note was impaired and the breath sounds were weak, but bronchial in character. The physical signs over the right side of the chest were normal, except that the heart could be seen beating over the second, third, and fourth spaces on the right side internally to the right nipple line, with the heart's apex beat in the fourth space midway between the right nipple line and the right border of the sternum. The impulse was somewhat heaving in character. On listening at the apex a well-marked systolic murmur was heard, which was only conducted inwards as far as the middle of the sternum. There was nothing abnormal in the urine, he had a fairly good appetite, and his bowels were regular. There was no oedema anywhere, and there were no dilated veins and no enlarged glands. As the patient had all the signs of an extensive effusion into the left pleural cavity, an attempt was made on the day after his admission to aspirate the chest in the sixth space in the mid-axillary line. An ordinary bottle aspirator was used with a moderate-sized needle; but as nothing but a little blood was drawn off the needle was again inserted on the same day, this time just internally to the angle of the left scapula, with the same result. The blood drawn off contained nothing but corpuscles. The temperature was 100.2° F. on his admission, and varied between that point and 98° for the next few days, and after that kept below 100° for some days. Soon after admission he was noticed to have a slight prominence of the chest wall in the left mammary region, which gradually became more marked, and on comparing a tracing of the chest wall taken on Jan. 12th, 1895, with one taken a month previously a considerable difference could be noticed in the size of the left side of the chest, especially in the anterior part. His general condition altered very little during this time; the temperature chart from Dec. 23rd to 30th showed an evening rise of nearly 101°, with a morning fall to normal, but from the latter date till his death his temperature did not rise above 100°, and after Jan. 1st or 2nd it never rose above normal. His pulse during the whole time he was in the hospital was rapid, on an average 120 to the minute, with the respiration 30 per minute. On Jan. 3d

an exploring needle was again introduced (this time into the left side of the chest in front), but with a regressive result. On the 15th some oedema of the chest wall in the left mammary region was noticed, which gradually increased. About this time, also, some dilated veins were noticed in the left axilla, and both external jugular veins were found to be distended; there was also some distension of the veins of the forehead at this time. From the 15th till the time of his death the patient passed very small quantities of urine, which was of high specific gravity and contained a trace of albumen on two occasions, but at other times was normal. On the 29th some oedema of the lower part of the back on the left side was noticed, that on the front of the chest being more marked; there was also some on the left side of the face. He now could only lie on the left side, being unable to breathe in any other position. On Feb. 2nd a small, rounded, almost fluctuating swelling was found just over the anterior surface of the head of the right humerus; it was painless, and the skin over it showed no signs of inflammation. On puncturing the tumour a little blood escaped, which on microscopical examination was found to contain cells of a sarcomatous nature. The dullness on percussion, loss of vocal fremitus, &c. now extended over to the right as far as a line drawn downwards from the middle of the right clavicle to the right nipple, and then to the costal margin, the heart's apex beat being just to the left of the right nipple in the fourth space. The signs were limited to the left side behind. From this time the patient became rather rapidly worse, the oedema increasing and the dyspnoea being more marked; he, however, apparently did not suffer any pain and slept well. The growth at the head of the humerus increased slowly in size, and another small tumour was found on Feb. 10th just below the left scapula, attached to a rib. He became delirious on the evening of the 18th, and died the next morning.

At the post-mortem examination the diaphragm on the left side was found to be very much depressed by, and the whole of the left side of the thoracic cavity filled with, an extremely soft growth; it was dark-brown in colour and enclosed in a capsule formed apparently of thickened pleura, which was firmly attached to the chest wall everywhere. At the upper and anterior part of the tumour, and continuous with it, was found a layer of collapsed lung about half an inch thick, seven inches long, and four inches wide at its upper part and narrower below. The heart and pericardium were displaced to the right, as was also the right lung. The two former were healthy, but the right lung contained a small growth about the size of a marble on its posterior surface. The liver contained a few small growths about the size of peas scattered through its substance. All the other organs were healthy. There were no enlarged glands, except one in the anterior mediastinum. Microscopic examination of the tumour showed it to be a round-celled sarcoma, which was rapidly degenerating.

Remarks by Dr. POORE.—The great interest of this case consists in the impossibility of diagnosis in the early stages. The history was that of an acute onset, and the physical signs on admission were those of effusion into the left pleura. Even after the failure of aspiration, which necessarily aroused one's suspicion as to the true cause of the trouble, it was hard to believe that such failure was not due to some mechanical condition—such as profuse and oedematous adhesions—which prevented the flow of the fluid from the pleura. The physical signs were uniform in character, and there were no patches of dullness and resonance or of diminished and increased vocal fremitus, such as are common in growths in the lung. The necropsy, which revealed a soft pultaceous tumour uniformly distending the visceral pleura, fully accounted for the physical signs during life. There was a history of very slight hæmoptysis, but this was never repeated and merely gave rise to the suspicion that there was tubercle as well as fluid. When, towards the end, there appeared marked oedema of the chest and marked distension of the veins on the left side of the face and chest, and this without any rise of temperature, the diagnosis became almost certain, and with the appearance of the soft tumours on the neck of the humerus and one of the ribs one felt quite sure as to what would be found post mortem. It is interesting to note that the weight of the patient, which was 6 st. 11 lb. on admission, fell to 6 st. 7½ lb. on Dec. 22nd, 1894, and rose to 7 st. 2½ lb. on Jan. 14th, 1895. The last weight recorded (on Jan. 22nd) was 7 st.

NORTH DEVON INFIRMARY.

A CASE OF INJURY TO THE ABDOMEN AND LEFT LUNG;
FREQUENT ASPIRATIONS, WITH SUBSEQUENT
RECOVERY; REMARKS.

(Under the care of Mr. JOHN R. HARPER.)

WE are pleased to place on record the account of the following case of severe abdominal injury. The patient was closely and skilfully watched and judiciously treated, and the description forms a useful addition to the few cases of the kind satisfactorily described in our literature. With regard to the diagnosis Mr. Harper was of opinion that the spleen was ruptured by the blow; the injury was directly over that organ, and, in addition, the amount of shock appears to have been considerable and the pain great. It is possible that there was a small rupture of the spleen, but it is more probable, we think, that the large collection which required to be tapped only twelve days after admission was retro-peritoneal and due to a rupture of the kidney. The blood which escapes in consequence of a rupture of the normal spleen passes through the thin capsule into the peritoneal cavity, where it may occasionally be limited by adhesions, and thus produce a swelling similar to that described. A case was under the care of Mr. Morgan¹ for rupture of the spleen and the patient died twelve days after the injury; the blood around the spleen had undergone but slight change, although it was localised by adhesions. The presence of urea in the fluid removed is of importance as confirmatory of this view. The absence of hæmaturia is at first sight against it, but this is not always present under such circumstances, for the laceration may be deep enough to cause considerable extravasation of blood, but as it has not extended into the pelvis of the kidney no blood escapes in the urine. The complication of effusion into the pleura is not uncommon after severe injuries to the upper part of the abdomen.

On Oct. 6th, 1894, when playing football, a man aged twenty-four whilst running was struck with great force in the upper and left side of his abdomen by an opponent's head. He was knocked down by the force of the blow and had to be carried off the ground to the pavilion, where he was examined by a medical man, but beyond marked tenderness in the left hypochondrium nothing abnormal could be detected. He had no fractured rib as far as could be made out; his pulse was good, but he complained of feeling a little faint; his pain soon passed off. He was advised to desist from playing, though, contrary to advice, he joined in the start of the second half, but soon had to retire. He afterwards drove back with the rest of the team to the hotel, and had partly dressed himself when he was taken suddenly with very acute pain in the abdomen; he fainted and was laid upon a bed, and medical assistance was sent for. He was found lying on the bed in great pain, his face pallid and covered with a cold sweat. His pulse was feeble and easily compressed. He localised all his pain below the ribs on the left side, where the full force of the blow had been spent; it was paroxysmal in character, the relief between the attacks being slight. He was very restless, yawning and throwing his arms about. He retched continually and once spat up a little frothy mucus tinged with blood. The abdomen was kept very tense, and pressure caused great pain. The pain was to some extent relieved by hot fomentations and turpentine. An opium pill (1 gr.) was given him. After an hour he rallied sufficiently to be moved carefully in a cab to the North Devon Infirmary. On admission he was at once put to bed, hot-water bottles were applied to his feet, and an injection of morphia was given. Laudanum applied on hot flannels was also ordered. The urine was drawn off by catheter; it contained no blood and was normal. His pulse had much improved and was now about 90. He himself felt better and almost free from pain. His abdomen could now be examined more carefully. There was an ill-defined fulness seen in the left side below the costal margins; some slight evidence of bruising was evident. The breathing was mainly thoracic. Palpation was rendered difficult owing to the rigidity of the abdominal muscles. There was very marked tenderness below the rib margins on the left side; percussion in this situation gave a dull note over an area about two inches wide and about three in depth. It appeared to be due to an increase downwards

in the area of splenic dulness. No fractured rib could be made out. He was given ice to suck and was kept under the influence of morphia. On one occasion after swallowing a teaspoonful of ice-cold water an intense pain was produced in his left side; it lasted a few minutes. On the following morning he appeared to be much the same, had had a fairly good night, and had been sick once, the vomited matter simply being bilious in character and containing no blood. He said he felt much better. The temperature was 100° F. and the pulse 96. The local condition was much the same—viz., extreme tenderness on pressure over the dull area, rigidity of the muscles was still marked, and there was some tympanites, with diminution of liver dulness. He was kept on a milk diet. For the next few days there was not much alteration in him. Locally there were all the signs of localised peritonitis; the dulness in the left side was increasing downwards and forwards, and no fluctuation could be made out. His general condition was better, but the tympanites caused him some discomfort, which was not relieved by enemata. The temperature varied from 100° to 101.5°. On Oct. 12th fluid was detected in the left pleura, reaching in front to the lower border of the third rib and behind to the spine of the scapula. The cardiac impulse was displaced slightly inwards. His breathing was a little quickened, and he complained of being "tight on his chest." The temperature was 102.5°. The pleural cavity was aspirated at the angle of the scapula, and about sixteen ounces of very deeply blood-stained fluid were withdrawn. The abdominal swelling had been gradually increasing in size, but it was not till Oct. 16th that well defined fluctuation could be made out. He still had considerable pain on pressure over the swelling. His pleura had filled to the level of the fourth rib. His general condition began to get worse; his tongue was coated, the breathing embarrassed—about 36 to the minute—and the temperature 102°. On Oct. 18th he was put under chloroform and examined. There was a distinct fluid swelling in the left hypochondrium, reaching from directly below the rib margin forward to the right of the median line, and extending down on a level with the umbilicus and across the left side of the abdomen. The whole area was uniformly dull, the dulness merging into that of the pleura, so that there was a dull area reaching from the fourth rib to the level of the umbilicus. His discomfort was so great that it was thought wise to aspirate the abdominal swelling, and the site chosen was two inches below the ribs and one inch behind the nipple line. About seventy-seven ounces of fluid were removed; the sac was not emptied, and a bandage was applied round his waist. The fluid was dark-green in colour and of a fairly thick consistence, with an alkaline reaction, sp. gr. 1011, and contained albumen in considerable quantities; there was a small quantity of urea (1 per cent.). The colour was due to altered blood pigment, chiefly methæmoglobin. Bile pigment and salts were tested for, with a negative result. Microscopically, masses of blood pigment could be seen; there were no definite crystals of hæmatoidin, but a few well-defined tyrosin crystals. On examination the following day the swelling was found to be nearly as large as previously to the tapping, but as yet there was no distension, which had made him so uncomfortable. He was in no pain. On Oct. 20th the pleura was aspirated, and forty-six ounces were removed, only slightly stained with blood. On the 23rd the fluid swelling was increasing, and abdominal distension very marked; he was in pain and very uncomfortable. The temperature was 102.5° and the pulse 110. The face was pale and haggard. The cavity was aspirated close to the former site, and sixty ounces of fluid of a specific gravity of 1010 and of a similar colour to the former were withdrawn. On Nov. 1st the fluid in the pleura, not having diminished, was aspirated; this time twenty-four ounces of clear serum were obtained. On the following day the abdominal cavity, which had again refilled, was aspirated, the quantity this time being 100 oz., of sp. gr. 1007 and not quite so dark a green colour. A good stout binder was applied. The swelling gradually increased till on Nov. 11th it had to be again relieved. Sixty-four ounces of a similar character were removed. After this date he required no further operative interference. He was put upon ten grains of diuretin every four hours for a few days, at first with apparent benefit, as in the first twenty-four hours he passed 115 oz. of urine. The fluid left in the pleura began to be slowly absorbed, and the abdominal cyst did not refill. His general health rapidly improved, so that by the end of the first week in December he was allowed to get up. On Dec. 21st he went home. His general

¹ Guy's Hospital Reports, 1844, p. 487.

health was excellent. There was a little thickening of the pleura at the left base and some slight displacement of the cardiac impulse inwards was evident; otherwise the chest was normal. A well-defined swelling could be felt below the rib margin for about two inches, which was dull on percussion, but no fluctuation could be obtained. On Jan. 22nd, 1895, he reported himself by letter as being in excellent health and stated that he had no trouble or inconvenience whatever from his side. On March 23rd he was seen by Mr. Penny, house surgeon. He was then at work and in good health, but had "a lump in his side."

Remarks by Mr. HARPER.—I have thought it best to report this case rather fully, as I have been unable to discover any case resembling it. Rupture of the spleen is in so many instances followed by rapid death that it seems to be advisable to put on record any in which recovery has taken place. In this case, fortunately, the associated lesions were not very grave; the one complication—probably a slight rupture on the surface of the lung into the pleura, which set up a certain irritation and was followed by effusion of serous fluid—was the only one to contend with. The injury to the spleen could not have been very extensive and could not have extended beyond the capsule of the organ. The hemorrhage appears to have been confined to within the capsule, which must have been gradually distended. The character of the fluid removed from the abdominal swelling is interesting from the fact of its containing tyrosin crystals. Quain, in his recent edition of the "Dictionary of Medicine," says: "Tyrosin is present in small amount normally in the spleen." The resulting lesions seem to have been due to the effect of contusion rather than fracture of the rib, as no evidence of the latter could be made out. From the abdomen 302 oz. of fluid were removed, and from the pleura eighty-nine ounces.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Carcinoma of Ureter.—Congenital Obliteration of Bile duct.—Sarcoma of Breast.—Carcinoma of Bed of Thumb-nail.—Carcinoma of Stomach.—Duodenal Ulcers in Women.—Cirrhosis of Liver in Child.—Secondary Intra-thoracic Sarcoma.—Exhibition of Specimens.

An ordinary meeting of this society was held on April 2nd, Dr. FAY, President, being in the chair.

Dr. VOELCKER related a case of Primary Carcinoma of the Ureter. The specimen was obtained from a man aged sixty-eight who was admitted into the Middlesex Hospital under the care of Dr. Cayley on Dec. 7th, 1894. He had never been laid up except in 1892, when he had influenza. Four months before admission he noticed a discolouration of his urine. On admission he was a well-built man with cedema of the left ankle. He complained of pain across the loins and of nausea, and was unable to take solid food. The liver was enlarged, nodular, and tender, and there was a resistance to be felt in the left iliac fossa. The urine was acid and contained a blood-clot. A fortnight after admission there was considerable hæmaturia and the patient had lost 18 lb. in weight in the last three months. The prominent symptom was pain over the liver; the liver was enlarged considerably, but the blood disappeared from the urine. Towards the end there was rapid loss of weight, 14 lb. being lost in as many days. The patient died on Jan. 20th, 1895. At the necropsy the body was fairly nourished; there was marked cedema of the left leg, and to a less degree of the right leg also. There was slight jaundice. The pericardium was adherent. Hypertrophy of the left ventricle was noticed and atheroma of the aorta was also present. The liver weighed 8 lb. 14 oz. and was much enlarged. The left lobe was almost replaced by soft pale new growth, and numerous nodules of similar growth were present in the right lobe. The nodules were not umbilicated. The gall-bladder was natural. The right kidney was natural; the left was only about one-third the size of the right and showed hydronephrosis. The left ureter was dilated. The lower two inches of the ureter were the seat of a new growth which formed delicate villous processes projecting into the ureter, and were blood-stained. The bladder was quite free from

growth, but a small blood-clot projected into it from the left ureter. The lumbar glands on the left side were infiltrated with growth and also the pelvic glands near the lower end of the ureter. There was a small nodule of growth in the upper lobe of the right lung. Microscopical examination of the growth in the ureter showed a typical papillo-carcinoma (villous cancer) of the ureter. The growths in the liver showed a similar structure. The epithelial cells were strikingly pyriform. No similar specimen had been recorded in the Transactions of the Pathological Society, and he had been unable to find any reference to a similar case either at home or abroad. Dr. Murchison¹ recorded a case of villous tumours in the pelves of each kidney associated with similar growths in the bladder around the orifices of each ureter. The structure of the growth was similar to that presented by a villous carcinoma of the bladder. The reasons for regarding the growth in the ureter as primary were the structure of the growth and of the deposits in the liver, the infiltration of the lymphatic glands on the left side of the aorta, the absence of any infiltration of the ureter from outside, the history of hæmaturia, and the presence of cedema in the left foot. The infiltration of the liver was unusual, for malignant disease of the bladder was rarely followed by secondary deposits in the liver. The small size of the left kidney might possibly be due to long-standing hydronephrosis induced by some injury to the lower end of the left ureter, possibly by a calculus lodging there, and at that situation a new growth developed later.—Mr. TARGETT regarded the specimen as a rare and interesting one. Villous growths in the bladder were not common, but were very malignant, and the secondary deposits strikingly resembled the primary growth. In one case of secondary growths in the lung, the villous processes were infolded and covered with epithelium precisely like that of the bladder. Secondary growths in the ureter were not uncommon; they might penetrate the tube from outside and either ascend or descend along it.—Mr. BOWLEY said that the bladder near the lower end of the ureter was a usual site for these tumours, the epithelium at the lowermost end of the ureter being of the vesical type.—Dr. VOELCKER, in reply, said that the growth did not commence at the lip of the ureter, for nothing could be seen of the growth from the interior of the bladder. The secondary growths were like those described by Mr. Targett.

Dr. FRANCIS HAWKINS (Reading) exhibited a specimen showing Congenital Obliteration of the Ductus Communis Choledochus. This duct was obliterated and appeared as a mere thread about one inch before joining the duodenum. The hepatic and cystic ducts were pervious, as was also the ductus communis choledochus for nearly an inch before becoming obliterated. The gall-bladder was not enlarged and was empty. The liver was enlarged, very firm, and of a dark olive-green colour, with fibrous bands running over the surface, which was slightly irregular. The blood-vessels were normal. The pancreatic duct was pervious and the opening into the duodenum was seen. Microscopical examination on section of the liver showed it to be cirrhotic. There was a right inguinal hernia containing the cæcum and appendix. There was also a small localised empyema at the left pulmonary base. The specimen was removed from a male child aged at death four months and two weeks, who was admitted into the Royal Berkshire Hospital suffering from jaundice, which had first been noticed eight days after birth. The jaundice was of a deep olive colour and the stools were white. Hæmorrhage from the mouth occurred on two occasions and epistaxis once. The family history was not important. Only two similar cases had been shown before the society, and from a diagrammatic representation of the local condition of obliteration of the bile-ducts made by Dr. John Thomson of Edinburgh it would appear that, including the two cases above mentioned, only six were recorded in medical literature where the ductus communis choledochus was alone obstructed. The cause of the jaundice was thought to be due to the change in the liver itself owing to the bile-ducts becoming constricted and obliterated. The cystic and hepatic ducts were pervious, and yet contained no bile.

Mr. J. JACKSON CLARKE described the histology of a Lobulated Growth of the Breast removed by Mr. Edmund Owen from a middle-aged woman. It was a typical alveolar sarcoma free from ulceration. Most of the cells of the tumour contained intranuclear bodies which were not found

¹ Transactions of the Pathological Society, vol. xxi.

in normal nuclei. These bodies were stained reddish-yellow by the hæmatoxylin-eosin method, and a brownish-red by Biondi's method. They appeared to contain one or more vacuoles, and most of them were provided with stiff peripheral processes which in many cases terminated in a round knob. Some of the intranuclear bodies were attached by a pedicle to the nuclear membrane. They attained a size averaging ten micro-millimetres, and the larger the intranuclear body the smaller was the amount of chromatin in the nucleus. Some of the larger bodies could be traced in the act of escaping from the nucleus into the cytoplasm of the cell or into intercellular spaces. Having escaped, they became enlarged and usually chromatin appeared within them, and so was constituted a series of forms leading up to the cells with giant mitoses. The latter entirely corresponded with bodies he had described in squamous epithelioma² and in sarcomata as free and sporing parasites, but they presented two important additional features—that is, besides the forms of sporing previously described by Mr. Clarke, ciliated zoospores and acinetæ embryos could be detected. The latter were identical in appearance with the smallest of the intranuclear bodies, and the former closely resembled some of the bodies described by Mr. Clarke in vaccinia.³ He had observed in all the cancers and sarcomas he had recently described intranuclear bodies similar to but less distinct than those in this sarcoma. He concluded that they represented an early phase of the parasites he had previously described. Up to the present time the only logical course had been to refer the parasites to the sporozoa. As he had stated elsewhere, and as had recently been demonstrated by Sanfelice,⁴ those who recognised only a few of the forms of the parasites of cancer could not logically refer them to the protozoa at all. They might just as well belong to the protophyta. In investigating the so-called psorosperms of the ureter he had been able to refer them to the protozoa by the character of their ectosarc, their nuclear forms, and mode of sporing. And in the absence of the special characters of the suctoria (ciliated swarm spores and acinetæ forms) the only logical position was to refer them to the sporozoa; in this he had recently been confirmed by von Kahliden.⁵ In cancer and sarcoma many of the parasites were identical in form with the psorosperms of the ureter, and, in spite of careful search, until now he had been unable to find ciliated spores and acinetæ embryos, so that the logical conclusion was that they were to be counted as sporozoa. Now, however, in the presence of the ciliated and tentaculiferous forms a modification of the position was necessary, and the parasites could only be referred to the suctoria. The change might prove to be no great one. It was quite possible that the suctoria formed a link between the sporozoa and the ciliata. This was for biologists to determine. The result of the examination of this sarcoma was quite in harmony with what Mr. Clarke had already advanced with regard to cancer and sarcoma. It was noteworthy that the parasites of variola and vaccinia were identical in form with many of the phases of the parasites in this sarcoma. Syphilis, again, constituted another link between infective processes and malignant neoplasms. Doehle⁶ had observed flagellates in the blood in primary syphilis, and Mr. Clarke had found bodies similar to the parasites of variola, cancer, and sarcoma in the primary, secondary, and tertiary lesions of syphilis. A few words were to be added with regard to molluscum contagiosum. Mr. Hutchinson⁷ had brought forward an observation made by Mr. Hitchens, by which it appeared that this disease had been communicated by a dog to a human being. This evidence was confirmatory of the careful work of Neisser and L. Pfeiffer. A still further observation tending to show the parasitic nature of this disease had been made by Mr. Clarke.⁸ Some material obtained from molluscum lesions was given to him by Mr. Malcolm Morris (a firm believer in the parasitic nature of this disease), and was placed in a moist chamber. After five days numerous actively moving flagellates were present, and there was good evidence that the latter were produced from the molluscum corpuscles.—Mr. SHATTUCK said that before the society could criticise the opinions put forward by Mr. Clarke it was necessary that the facts should be corroborated. The specimens should be

submitted to the Morbid Growths Committee in order that others should be convinced of the accuracy of the facts and observations recorded in the paper. Mr. Ballance and he had been cultivating molluscum contagiosum on wet sand under sterile conditions without obtaining any growth of protozoa.—Dr. KANTHACK said that Drs. Klein and Copeman had failed to find protozoa in the rabbit's cornea after vaccination. He himself and two others had produced blisters on themselves in the ordinary way with cantharides, and in the blisters were found a large number of bodies identical with these so-called protozoa. The majority of those who were constantly finding protozoa appeared to work without any control observations whatsoever. In a case of sero-cystic disease of the breast he found in some large cells leucocytes in all stages of degeneration, which stained readily with acid fuchsin and eosin, and other dyes. A catalogue of diseases had been enumerated in which protozoa had been found, but he asked where the specificity of these diseases came in if all were caused by the same organism.—Mr. CLARKE, in reply, consented to permit his specimens to be examined and reported on by the Morbid Growths' Committee provided that the photographs of the specimens which he supplied were published along with that committee's report. He lodged a complaint against the manner in which he had been treated on previous occasions by the Morbid Growths Committee. He claimed that for some years he had studied this subject, and had compared his results with control examinations of normal tissues.

Mr. EDGAR WILLETT showed a Tumour growing from the Ungual Phalanx of the Thumb which had been removed by operation from an old woman aged eighty. From the structure he considered it to be carcinomatous. It had grown slowly for seven years. There was no glandular enlargement at the time of operation, nor within one year afterwards. Three years later secondary deposits had formed in the axilla.—Mr. TARGETT said the specimen was one of squamous-celled carcinoma with extensive processes the central parts of which were breaking down.

Mr. BIDWELL showed a specimen of Gastro-enterostomy for Pyloric Cancer. The jejunum was firmly united to the stomach, but the patient had died ten days after the operation from broncho-pneumonia. There was a huge mass of cancer involving the pyloric end of the stomach, and the jejunum, at a point two inches from the duodenum, had been united to the middle of the posterior surface of the stomach by Halsted's method for lateral intestinal anastomosis. Food had been taken in good quantity immediately after the operation, and there was no sign of any peritoneal irritation around the anastomosis. The opening, though small, had not contracted during life.

Dr. LEE DICKINSON showed a specimen of Acute Perforating Duodenal Ulcer in a woman, and three other similar cases in women were described. These ulcers were known to be much commoner in men, in whom no particular diathesis had been recognised; and the few women whom they affected were generally neither young nor anæmic, markedly differing from the chlorotic females who were the usual subjects of perforating gastric ulcer. Not one of the four women whose cases were described was anæmic. It was suggested that, though perforating ulcers of the stomach and first part of the duodenum appeared so similar in their morbid anatomy, they depended for their initiation upon a different diathesis, and anæmia had no share in the causation of the duodenal ulcer. Some remarks were subjoined upon subphrenic abscess, which was a comparatively frequent result of gastric perforation. Duodenal perforation, on the contrary, almost always caused diffuse peritonitis; but a case was quoted, however, in which a subphrenic abscess was due to this cause. One was specially remarkable because the abscess was to the left of the falciform ligament.

Dr. F. PARKES WEBER showed a specimen of Cirrhosis of the Liver in a Child. The liver and spleen were those of a girl aged fourteen, who had been more or less jaundiced all her life. For her age she was very ill-developed, appearing much younger. The skin was considerably pigmented (probably a result of the chronic jaundice). The liver could be felt below the costal margin and the spleen reached to below the anterior superior iliac spine. For about ten weeks before death there was considerable fever of an irregular type, commencing a few days before ascites was first detected. The superficial abdominal veins were distended. At the necropsy the fluid in the peritoneum was clear. The liver was green, hard, hob-nailed, and weighed 26½ oz. Microscopic examination showed a large amount of fibrous tissue

² Morbid growths—sporozoa.

situated much as in ordinary cirrhosis, dividing the gland substance into unequal compartments and sometimes invading the lobules, entering between the individual hepatic cells. In the orange-rubin specimens green inspissated bile could be seen situated between or in the hepatic cells. The gall-bladder contained some clear, almost colourless fluid. There was no perihepatitis. The spleen, uniformly enlarged, weighed 20½ ounces; on section its substance appeared too firm, but otherwise natural; the microscope showed considerable increase in fibrous tissue and considerable deposit of pigment in some of the trabeculae. The lymph glands, especially those of the hilum of the liver, were somewhat enlarged and much pigmented. The common bile-duct was, unfortunately, not examined. The mother of the child died from phthisis and at the period of her life when the child was born was a great drunkard. The late development of the ascites was noteworthy, and the great size of the spleen was interesting from both a pathological and a clinical point of view. Perhaps ordinary hepatic cirrhosis affecting the growing tissues of a child might cause a much greater relative enlargement of the spleen than in an adult.

Mr. H. B. MEAKIN showed a large Sarcoma filling the left pleura; there was also another mass infiltrating the spine. It was obtained from a girl aged fifteen, who one year previously underwent amputation of the right thigh for a subperiosteal sarcoma of the lower end of the femur. Notwithstanding the enormous size of the growth there had been very little pain and discomfort, and it was noted that the inhalation of oxygen relieved in a marked degree the attacks of dyspnoea to which she had been liable.

The following card specimens were shown:—

Dr. A. A. KANTHACK: (1) (with Mr. C. B. LOCKWOOD) Psammoma of Tunica Vaginalis; (2) Psammoma (?) of Mesentery; (3) Psammoma of Vermiform Appendix and Ovary; (4) (with Mr. E. L. LLOYD) Metaplasia of Omental Epithelium into Squamous Epithelium; (5) (with Dr. C. P. WHITE) Giant Cells in Innocent and Malignant Tumours of Epithelial Origin.

Dr. VOELCKER: Ulceration of Gall-bladder in Typhoid Fever.

Mr. H. SNOW: Malignant Reversion of Mammary Cystic Fibromata.

Dr. LEE DICKINSON: Solitary Kidney with Two Ureters.

Dr. F. HAWKINS: Adhesion of the Vocal Cords and Laryngeal Stenosis in a case of Leprosy.

HUNTERIAN SOCIETY.

Rheumatoid Arthritis.

An ordinary meeting of this society was held on March 27th at the London Institution, Mr. CHARTERS J. SYMONDS, President, being in the chair.

Dr. FORTESCUE FOX read a paper on the varieties of Rheumatoid Arthritis. He said that the cases naturally divided themselves into three groups: (1) those occurring during childhood and young life; (2) those at or about the climacteric in women; and (3) those occurring in elderly people—say, over sixty. He narrated the particulars of one or two typical cases in each class. He considered briefly the pathology of the disease, noting especially its constitutional and nervous origin, while considering the relation which anaemia, tubercle, shock, &c., bore to it. Prognosis, Dr. Fox considered, was better in the cases advanced in life than in those occurring in youth. Treatment was largely concerned with warm baths and massage, while arsenic and iron were the most reliable drugs.

Dr. FRED. J. SMITH thought that Dr. Fox's paper threw much light on the numerous arthritic cases occurring amongst hospital out-patients which would not range themselves under the heading of gout or rheumatism as type cases; he thought that treatment from an out-patient view was very disappointing.

Sir HUGH BEEVOR agreed with Dr. Smith's views and asked for further information on the morbid anatomy, hinting at the possibility of changes being found in the spinal cord as marked as those found in other acknowledged cord diseases.

Dr. LOUIS BLANC (Aix-les-Bains) remarked on the relative frequency of the disease in England compared with France, and thought that one factor might be the imperfect drying and exercise after the morning tub.

Dr. A. GARROD regretted the absence of knowledge of the

anatomical condition of the affected joints in young people, he did not agree that the prognosis was worse in youth. To the syrup of the iodide of iron he was inclined to give the first place among drugs, arsenic being the next most useful; but he agreed with Dr. Smith that treatment in out-patients was disappointing because many months rather than a few weeks were required.

Dr. GLOVER drew special attention to anaemia as a contributory factor, and thought that measures conducive to the improvement of the blood were the best to be employed; he agreed with Dr. Garrod and others that a full diet, stimulating in character, was an essential feature.

Dr. Fox replied, and the meeting adjourned.

HARVEIAN SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on March 21st, the President, Sir JOHN WILLIAMS, Bart., being in the chair.

Dr. LEONARD GUTHRIE showed two cases of Scaphocephalus in children, one of whom was the subject of rickets. The fontanelles were said to have been closed at birth. He thought the cause was synostosis of the sagittal suture.—Dr. SHUTTLEWORTH related similar instances and showed drawings.—Mr. GORDON BRODIE referred to a case under his care in which there was also exophthalmic goitre.

Mr. EDMUND OWEN showed a boy convalescent from Pyæmia after Osteomyelitis. He commented on the frequency with which this event occurred in children and the readiness with which they recovered.

Dr. WILLIAM HILL showed a case of Disease of the Accessory Sinuses of the Nose, caused, as he thought, by dental irritation.—Dr. C. W. CHAPMAN thought rather that the inflammation had extended from the nose.—Dr. PEGLER believed that the mischief was active in the posterior ethmoidal cells and advised exploration of the maxillary antrum by way of the inferior meatus.—Mr. MAYO COLLIER also commented on the case.

Dr. G. A. SUTHERLAND showed a case of Pulmonary Fibrosis in a youth with Phthisis.—Dr. C. W. CHAPMAN remarked upon the chronic nature of this condition and related a case of extreme displacement of the heart without serious impairment of health.

Mr. MAYO COLLIER showed two cases of Hallux Rigidus. He described the origin of flatfoot in this condition and the changes in the articular surfaces.—Dr. GUTHRIE inquired as to the cause of spasm of the short flexors in ballux rigidus and suggested that the partial subluxation of the joint was the first step in the deformity. Such subluxations of the toe joints were known to be the cause of severe pain.

LIVERPOOL MEDICAL INSTITUTION.

Perforating Ulcer of the Stomach; Gastrostomy; Recovery.—Complete Removal of the Internal Semilunar Cartilage.—Removal of Loose Cartilage from the Intercondyloid Notch.—Neuritis from Poisoning by Carbon Monoxide.—On the Mental Aspect of some Traumatic Neuroses.

A MEETING of this society was held on March 28th, the President, Mr. CHAUNCEY PUZEY, F.R.C.S., being in the chair.

Mr. PAUL related a case where he had successfully operated for a Perforating Gastric Ulcer.

Mr. BANKS showed a patient from whom he had removed the Internal Semilunar Cartilage. An incision was made along the inner side of the knee-joint, and after the strong internal lateral ligament had been divided the joint was easily opened up and the cartilage removed. The patient was now on a Thomas's splint and was gradually recovering the use of the leg.—Mr. BANKS also read notes of a case where he had removed a Loose Cartilage from the Knee-joint. He made an incision along the inner side of the joint, and without dividing the internal lateral ligament he was able to feel the loose body in the intercondyloid notch and to remove it.

Dr. GLYNN gave particulars of a case of Chronic Neuritis produced by the Inhalation of Carbon Monoxide. The patient, a boy aged sixteen years, was admitted into the Royal Infirmary on March 6th. He was quite unable to walk and had been confined to bed for five months. There was weakness of the muscles of the legs, especially the extensors of the feet;

there was tenderness of the muscles and loss of irritability to the faradaic current; and there was some loss of sensation and paræsthesia. The knee-jerks and plantar reflexes were absent; there was marked spasm of the gastrocnemii. The more ordinary causes of neuritis—lead, alcohol, diphtheria, and rheumatism—could be excluded, and the history of his illness pointed to the probability of carbon monoxide poisoning. The boy was an engine cleaner and worked in a shed where about twelve engines were cleaned every night. In this shed there was a furnace, and he had to carry red-hot coals from this furnace to start the engine fires; the engines took four hours to get up steam, and during that time he often found the fumes of the fires very irritating. Five months ago he began to have pains in the calves; a month later he had dyspnoea on exertion and swelling of the legs, his urine became albuminous, and he lost all power in his lower extremities. In the hospital he rapidly improved under iodide of potassium and hot fomentations to the legs. He regained the power of walking, though the extensors remained weak; the knee-jerks were still absent and he was unable to stand with his eyes closed. When first seen his blood was examined and the amount of hæmoglobin found to be normal, and the number of red cells was not diminished, so that the more direct effects of carbon monoxide poisoning were absent. The boy presented many of the marks of degeneration—smallness of stature, ill-developed ears, &c.—and hence was probably predisposed to disorders of the nervous system.

The paper of the evening was read by Mr. HERBERT PAGE (London) on the Mental Aspect of some Traumatic Neuroses. Having defined a traumatic neurosis as a disorder of the nervous system following injury, functional or dynamic in character, and independent of gross structural or as yet known lesion in the nervous centres, he pointed out that the evolution and elaborated structure of the nervous system as seen in man seemed to predispose it to instability of equilibrium. The close relationship of distant parts of the body through the agency of the nervous system made it unavoidable that prolonged physical pain should cause mental anxiety and derangement of the general health. Speaking of the periphery of the nerves and the nervous centres as respectively the two ends of the nervous system, Mr. Page showed how trifling physical injury at the periphery might lead in time to considerable mental disturbance and to the evil consequences thereof, while psychical shock acting on the cerebral cortex might bring about serious impairment of health by causing functional derangement of the organic processes of life. As instances of the former effects he cited cases of injury to extra-spinal structures. Railway collisions and kindred accidents associated with much terror provided examples of the neuroses beginning in central disturbance. It was a mistake to look on the symptoms of these cases as either imaginary or feigned, nor could treatment be successful if this were the view entertained of them. The close relationship of mind and body must not be forgotten, and due regard to the psychical element in all these nervous disturbances was essential for success in treatment. It was all-important, moreover, that diagnosis should be prompt, so that the patient might be saved from lines of treatment likely to perpetuate his ailments by reason of continued apprehension and introspection. The various determining factors in the traumatic neuroses were specially alluded to, and it was shown how suggestion might play a part in originating new phenomena and prolonging those which had arisen directly from the accident.—A most interesting discussion followed the paper, in which Mr. Puzey, Mr. Banks, Mr. A. Wiglesworth, Dr. Barr, Dr. Carter, Mr. Sheldon, Mr. Paul, and Dr. Davidson took part.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Hydroa Gestationis.—*Friedreich's Disease.*—*Protracted Typhoid Fever.*

A MEETING of this Section was held on March 22nd, Dr. W. G. SMITH, the President, being in the chair.

Dr. NINIAN FALKNER showed a case of *Hydroa Gestationis*. The patient, aged thirty-eight years, had been married twice, has had six children, and is now in the third month of her seventh pregnancy and the third attack of the

disease. The eruption commences at the end of the third month on the back of the wrists, and continues to advance until it covers all parts of the body; after delivery it disappears in about six weeks. This is the third time that Dr. Falkner has attended her. She states that it comes on only when she is carrying a male child.—The PRESIDENT said that he had seen this patient a year ago. She was pregnant at the time, and he had no doubt that it was a case of *hydroa gestationis*. He was not aware of any other cases of the same kind seen in Dublin except one by himself at the Adelaide Hospital dispensary.

Mr. M. J. NOLAN read a paper on Three Cases of *Friedreich's Disease* (*Hereditary Ataxy*) associated with *Genetous Idiocy*. The communication was illustrated by photographs. The ataxic subjects are aged respectively ten, fifteen, and twenty-two years, and are members of a family of eight, the remaining five being healthy and intelligent. There is a family history of tubercle, brain disease (*cerebellar*? maternal grandmother ataxic), and alcoholism. The father is a chronic drunkard. There is no syphilitic taint. The symptoms became evident in earliest infancy, and progressively developed from the lower to the upper limbs. They consist in jerky movements of the head, feet, and hands, "static ataxy" (*Friedreich*), and "ataxy of quiet action" (*Friedreich*), scanned speech, tremor and paresis of muscles, and "static" and "ataxic" nystagmus (*Friedreich*). In one case knee-jerk is retained; in one it is retained and exaggerated, and accompanied by ankle clonus; and in one it is lost. The girl has lateral curvature of the spine and arrest of sexual development. All are psychically asexual. The two oldest cases have large goitres. There is no clubfoot deformity (a non-essential symptom) or ocular disease; the integrity of the sphincters is preserved; there is no marked disorder of sensation (apart from varying degrees of analgesia irregularly distributed in two of the patients); the electrical reaction of the muscles is normal. The patients possess a very low degree of intelligence, but a marked tractability and good humour of an expansive type, without irritability or tendency to unprovoked mirth. All the symptoms, physical and psychical, are in inverse ratio to age—i.e., the youngest are the most affected. No previous cases have been recorded showing an association of *Friedreich's disease* with *genetous idiocy*. The mental condition is devoid of the waywardness, sexual depravity, and violent outbursts so common to idiots. The possibility of an extension of gliomatosis to the cerebral hemispheres (*idiotcy* so often arising from neuroglial sclerosis) is suggested as the explanation of this twin condition of *genetous ataxy* and *genetous idiocy*.

Dr. A. R. PARSONS read the notes of a case of *Typhoid Fever* in which *Pyrexia* was Prolonged for a lengthened period. He exhibited a temperature chart which extended over 290 days. The patient recovered.

Dr. NINIAN FALKNER read a note on a case of Prolonged *Typhoid Fever*, and exhibited a temperature chart for 119 days.—Dr. PURSER thought that Dr. Parsons' case differed materially from that of Dr. Falkner. In the latter there were several complications, and the case was that of a young child, in which the temperature increased much more easily. Dr. Parsons' case seemed to have been uncomplicated except for a short attack of pneumonia at the beginning.—The PRESIDENT thought that Dr. Parsons' chart was the longest on record, and that there was no doubt about the diagnosis from the full account given.—Dr. PARSONS, replying, said that Murchison gave 160 days as the longest chart of typhoid fever. He did not think the cause of the temperature was a suppurating mesenteric gland, as it probably would have burst into the peritoneal cavity and produced peritonitis, which the patient never had.—Dr. FALKNER, in reply, thought the complications in his case would have some effect on the temperature, but the patient had hæmorrhage on the seventy-second day, and diarrhoea with jelly-like motions till the ninetieth day, and also typhoid spots with pain, so that he was still of opinion that the typhoid fever lasted at least till the 120th day.

THE monthly meetings of the Royal Statistical Society during the remainder of the session 1894-95 (April 23rd, May 21st, and June 18th) will, by kind permission of the council of the institution, be held in the lecture theatres of the Royal United Service Institution, Whitehall, S.W., at 5 P.M. precisely.

Reviews and Notices of Books.

On Diseases of the Vermiform Appendix, with a Consideration of the Symptoms and Treatment of the Resulting Forms of Peritonitis. By HERBERT P. HAWKINS, M.A., M.D. Oxon., F.R.C.P., Assistant Physician to and Lecturer on Pathology at St. Thomas's Hospital, Assistant Physician to the London Fever Hospital, and late Radcliffe Travelling Fellow of the University of Oxford. London: Macmillan and Co. 1895.

We learn from the title-page that this was a dissertation presented to the University of Oxford for the degree of Doctor of Medicine in April, 1894, and in this respect it resembles Dr. Kelyack's *brochure*, which was a graduation thesis at the Victoria University. Dr. Hawkins has done a really valuable piece of work, and no one can read this essay without obtaining a clear idea of our present knowledge of this important subject. It is not that we are presented with original work or new views of the pathology or treatment of "appendicular peritonitis," but the great merit of the thesis lies in the really admirable manner in which the facts are presented. In many contributions on this subject much error has been mixed up with fact, and in some the influence of the writers' personal bias has largely affected their statements and arguments. And so this unprejudiced, precise, and critical survey of the actual facts is particularly valuable. The main points which Dr. Hawkins insists upon are that the appendix is the true source of all those cases which were formerly called iliac phlegmon and typhlitis; that in all cases the acute disease is a peritonitis which may be localised and plastic in character, ending in resolution, or localised and suppurative, ending in abscess, or from the first a generalised peritonitis. In all these forms alike the actual *causa causans* is the invasion of the peritoneum through the walls of the appendix by pathogenic organisms, of which the bacillus coli communis is by far the most important. This invasion of the appendix by micro-organisms may be the result of chronic catarrh of its mucous lining, or of the pressure of a concretion or of fluid in a cystic dilatation beyond a stricture, and it is largely aided by the functionless rudimentary state of the organ. Great stress is laid upon the fact that it is impossible with our present means to decide during the first two days of the disease what course the appendicular peritonitis will run. This is shown to have a great bearing on the question of treatment, for, while the commonest form of the disease—limited adhesive peritonitis—is practically free from all mortality when treated by medical measures only, the diffuse general peritonitis has a very heavy death-rate. The question of treatment is most judiciously dealt with, and without dogmatic assertion the author has given a most fair statement of the position of the question and of the points at issue between American and British surgeons. We have read this *brochure* with great pleasure, and we commend it to our readers as the most reliable statement of our present knowledge of this disease that has yet appeared.

On Some Symptoms which Simulate Disease of the Pelvic Organs in Women, and their Treatment by Allo-Piosto-Myo-Kinetics (Massage) and by Auto-Piosto-Myo-Kinetics (Self-Movements of Muscles under Pressure). By A. RABAGLIATI, M.A., M.D., F.R.C.S. Edin., Honorary Gynaecologist, and late Senior Honorary Surgeon, Bradford Infirmary. London: Baillière, Tindall, and Cox. 1895.

This little work aims at assigning a definite pathology to some of the symptoms met with in certain neurotic or hysterical women. The author endeavours to show that many of the pains and discomforts, of which these patients complain, are not really referable to the nervous system, as such a term as neurasthenia or neuralgia might seem to imply, but

that the affection is really one of the muscular system, and that it might, therefore, be more properly called a myalgia or myosis. He believes it to be of rheumatic origin, and suggests the name perimyositis rheumatica. An essential feature of the condition is a passive congestion of the muscles, or, rather, of the muscle-sheaths, brought about by a rheumatic state of the blood. One reason given in support of the view that rheumatism is the primary cause, is, that in rheumatism the synovial membranes are affected, and that in the cases under consideration he always finds tenderness of the synovial membrane of the articulation of the lower jaw. Similarly, he finds the sacro-iliac synchondroses affected, and believes that tenderness really due to the state of these joints is not unfrequently wrongly assigned to the corresponding ovary. Perverted nutrition is given as playing an important part in the causation of the disease, and consequently the author lays stress on careful attention to the diet in treating it. The special feature of his treatment, however, is the movements of various muscles by the patient herself, combined with pressure on them while they are made to contract. A series of photographs is given at the end of the book illustrating some of the principal movements that the patient is advised to make.

We are naturally inclined to be a little cautious in accepting any treatment as likely to prove a specific in some of these cases, which are generally recognised as being among the most obstinate and disheartening that the practitioner has to deal with. Still, there can be no reason why Dr. Rabagliati's method should not be tried. It can, we should think, do no harm, even if it fails, and in that respect contrasts favourably with surgical procedures of a mutilating nature, which have no doubt been too often employed, and employed not rarely unsuccessfully in the past.

The Treatment of Wounds, Ulcers, and Abscesses. By W. WATSON CHEYNE, M.B. Edin., F.R.S., F.R.C.S. Eng., Professor of Surgery in King's College, Surgeon to King's College Hospital. Edinburgh and London: Young J. Pentland. 1894.

SURGICAL students and those practitioners who have not yet familiarised themselves with the modern improvements in surgery will find in this volume an admirable guide to the practical application of antiseptic methods. Mr. Watson Cheyne entirely approves of the general doctrines of Sir Joseph Lister, his eminent predecessor at King's College, frequently quoting him and warmly advocating his employment of bactericides in preference to the intricate aseptic procedures adopted mainly by some Continental surgeons. The reader is continually reminded that careful attention to many details is absolutely essential to success, and these injunctions are emphasised by the assurance that unfavourable results must be attributed not to any inherent defect in the antiseptic system, or to any exceptional idiosyncrasy in the patient, but solely to some accidental oversight or neglect on the part of the operator himself. An acquaintance with at least the elements of practical bacteriology is, in fact, indispensable for a surgeon in order that he may be sufficiently convinced of the necessity of a conscientious and intelligent observance of the precautions required in antiseptic practice. About a hundred pages are devoted to the antiseptic management of wounds, including under that heading both incisions made by the surgeon and injuries inflicted in various ways and under diversified conditions. In cases of surgical incisions the preliminary stage is disinfection of the skin by washing, firstly, with soap and a 5 per cent. carbolic acid lotion containing also a 500th part of corrosive sublimate; and, secondly, with turpentine. The surgeon's hands are carefully treated in the same way, and all instruments are sterilised by two or three hours' immersion in a 5 per cent. carbolic acid lotion. During the progress of the operation

the wound is from time to time filled with a 1 in 2000 corrosive sublimate solution, bleeding from small vessels is checked by pressure or torsion, large veins and arteries are ligatured with catgut prepared by sulphurous acid and chromic acid, the skin is brought together with silk stitches or silver wire, and the junction is covered with a liberal supply of gauze impregnated with double cyanide of mercury and zinc and wetted with a 1 in 4000 corrosive sublimate or a 1 in 40 carbolic acid solution. In the majority of cases this dressing is left undisturbed for about ten days, by which time primary union is generally established.

As a clearly written, reliable, and handy exposition of the characteristic feature of modern surgery Mr. Watson Cheyne's work merits the highest commendation.

LIBRARY TABLE.

On Preservation of Health in India. By Sir J. FAYRER, K.C.S.I. London: Macmillan and Co.—This little book is a reprint of the substance of a lecture delivered to the students of the Engineering College at Cooper's Hill. The author begins by drawing attention to the size and extent of British India, a very necessary reminder, for there are still many people who think that if you live in Bombay you can pay morning calls in Madras. A short description of the various climates of India is then given and rules laid down for clothing, diet, the use of alcohol and tobacco, and the choice of the site for a dwelling-house. Sir Joseph Fayrer very properly lays stress upon the danger of being over anxious in regard to health and of undue physicking. Malaria is discussed, and rules given for avoiding, as far as may be, that scourge of India. Dysentery, cholera, and snake-bite are treated of, and directions given which a layman may carry out until the arrival of a medical man.

Brewery Companies. By H. S. Reprinted from the *Statist* for August-December, 1894. London: the *Statist* Office. 1895.—Many readers will learn with some surprise that there exist in the United Kingdom no fewer than 404 registered brewery companies, possessing a total authorised capital of upwards of £106,000,000. The three largest businesses are those of Arthur Guinness, Son, and Co., Limited (capital £6,000,000), Bass, Ratcliff, and Gretton, Limited (capital £4,030,000), and Samuel Allsopp and Sons, Limited (capital £3,700,000). The public interests involved in such undertakings are, of course, very great, whether from the point of view of the investor or the social reformer. The volume under consideration deals with the question mainly as affecting the investor, who will find in it copious details on the subject of the various companies' finance, production, and prospects. The work is well worthy of perusal by brewery shareholders.

MAGAZINES AND REVIEWS FOR APRIL.

The Practitioner.—This journal offers its usual amount of interesting and well-written matter. In the department of surgery Mr. Pearce Gould writes on Some Unusual Cases in the Surgery of the Breast, where, as he says, "the rules usually formulated to guide the surgeon in his treatment" were not adhered to, but with good results. Dr. Sansom writes an eminently practical paper on the Treatment of Nervous Disturbances of the Heart resulting from Influenza. Such are cardiac pain, irregular action, rapidity of heart beat, and slowness of the same. Dr. Cullingworth writes on the Local Treatment of Puerperal Fever; Dr. Skeritt on Caffeine as an Anti-spasmodic in Respiratory Affections; and Dr. Hewlett sends an interesting article on the Antitoxin Treatment of Tetanus. A retrospect of the past month, some reviews, an abstract of foreign journals, and practical

notes on medicine, therapeutics, and surgery make up a number well worth reading.

The Asclepiad.—Sir Benjamin Ward Richardson's quarterly is as usual marked by the author's well-known learning and lucidity of expression. The first paper deals with the Treatment of Uræmic and Dropsical Coma, the indications being to remove pressure (a) by bleeding and (b) by aspiration. The causes of coma in uræmia and dropsical conditions are discussed, and the circumstances in which bleeding is to be preferred to aspiration, and *vice versa*, are ably set forth. A Lecture on Health and Athletics follows, and in the *Opuscula Practica* some good sound rules are laid down for the Prevention of Consumptive Disease. Other points of interest are the notes on the Iodine Disinfecting Box and Tracheotomy in Diphtheria, suggesting that not only is tracheotomy curative by admitting air into the lungs, but by the fact that the air admitted no longer passes over a decomposing surface. The biographical notice is a careful and sympathetic review of the life of William Alexander Greenhill of Hastings, a true type of the literary and scholarlike medical man. Sir Benjamin Richardson is always happy in his articles on the medical and surgical art of the past, and in his quotations from the work of M. Bellotti, "The Hospital Surgeon," treating of the dressing of wounds speedily to prevent the access of air, he shows how in 1713 the embryo of antiseptic surgery was already conceived.

The Contemporary Review has several articles of interest, notably a review of Mr. Balfour's "Foundation of Belief" by Dr. Fairbairn, and a paper on "Canadian Copyright" by Mr. Hall Caine. The article which, however, concerns us most nearly from a medical point of view is "The Fiction of Sexuality," wherein Mr. James Ashcroft Noble says that the cry for more freedom in literature is really a cry for the removal of a certain healthy phase of public opinion. From our point of view the modern "sex novel" is as rightly condemned by this opinion as a detailed account of a post-mortem examination or a labour would be if published in a book intended primarily for lay readers.

The Humanitarian treats of various medical subjects in its usual outspoken way. Mr. F. St. John Ballen writes on the Prevention of Insanity, and, after passing in review the various methods which have been proposed to check the disease, comes to the conclusion that little can be done except to educate people more widely in the laws of hygiene as affecting insanity and its causes. Mr. G. T. Leicester has an earnest plea for the re-enactment of the Contagious Diseases Act, and the Rev. J. R. Byrns writes on Corporal Punishment in Schools. He calls it degrading, and talks about the "odious Eton swishing." From a personal knowledge of Eton boys we doubt whether any boy ever felt degraded by hearing that he was to "stay," or was hardened by being "swished."

The Westminster Magazine.—In the ever-present sex article, this time by Mr. G. P. Sykes, we find the following notable sentence (the italics are our own):—"The judicious author frequently accomplishes more than a dozen sermons; but when fools rush in to stop a gap the inevitable consequences are that the gap is widened and made worse than before." The future scholiast will doubtless quote this as a gloss upon "Yellow books" and the like. Mr. Sykes is a hard hitter. "Woman at the present epoch has persuaded herself that she is the salt of the earth as well as the sweet, that her intelligence, her faculties, and fads and crazes are greater than anything else in the evolutions of the *fin de siècle*." Miss Alice Law writes very charmingly about the late Christina Rossetti, and there are many reviews and an article on Schopenhauer.

THE LANCET.

LONDON: SATURDAY, APRIL 6, 1895.

THAT the problem of the poor is still with us is sufficiently proved by the Report of the Royal Commission on the Aged Poor. It is not that there are more poor, or that the poor are poorer than they were, but that society is more sensitive—more healthily and morally sensitive—on the subject. Some say that we are following the evil luxurious fashions of old Greece and Rome. Certainly there is far more luxury among us than is good for us. But, nevertheless, society is pervaded more and more with a sense of the miseries of poverty, such as probably has never before been felt by well-to-do people. They feel that they have a responsibility, not alone for themselves, but for others. To make "provision for one's own, and especially for one's own household," is a primary duty of humanity, enforced by Scripture in striking terms; but we have come to see that our duty does not stop there, but extends to unfortunate people—and even faulty people—and includes an obligation to do what in us lies to extricate them from the plight into which they have fallen by their very vices. This view is laid down very strongly in the separate report to the Commission by Mr. BROADHURST, who quotes with concurrence the following striking language of Professor ALFRED MARSHALL:

"While the problem of 1834 was the problem of pauperism, the problem of 1893 is the problem of poverty—that a man ought not to be allowed to live in a bad home, that extreme poverty should be regarded, not indeed as a crime, but as a thing so detrimental to the State that it should not be endured, and that everybody who, whether through his own fault or not, was incapable of keeping together a home that contributed to the well-being of the State, that person should, under the authority of the State, pass into a new form of life."

All will agree that society has great responsibilities for the existence of insanitary houses and even for those who live in them. But is there not in such language as the above an excessive estimate of what the State can do? Is it really possible for the State to take hold of a man and his wife who have proved themselves incapable of creating a healthy and happy home and to place them *volentes volentes* in a condition to make them "pass," to use Professor MARSHALL's remarkable language, by waving its wand, as it were, into "a new form of life"? This seems to us to be a sort of delusion of the State—an attribution to it of powers which it has not got of treating men as if they were not men, but pawns or machines. It seems to ignore the personal element altogether, forgetful that the man makes the home rather than the home the man—that "the mind is its own place."

The fact is, this Royal Commission has done no more than to bring into very vivid light the different views of poverty and its remedies which undoubtedly exist among people equally anxious to do all that is possible for the amelioration of the lot of the poor. In this investigation all sorts of experience and evidence have been brought together except

perhaps medical evidence, which is very scanty and which in some respects is the most important of all. We would venture to say that a few experienced and thoughtful medical officers of parishes in town and country could throw more light on the deep causes of poverty than either relieving officers or guardians, since they are brought into much closer contact with the poor and their homes in all the deep plights of life than any other persons whatever. The predominant note of the Report—that of the majority—is that the pauperism of the aged is not increasing, but rather decreasing, and that those who are in regular employment are able to make direct or indirect provision for old age as well as for sickness and other contingencies beyond the everyday needs of life. This is undoubtedly true. But it does not alter the fact that from some cause or other a large proportion of those above sixty-five have to apply for parish relief in one form or another; that, in round figures, three in ten of the population above this age are compelled to apply for such relief during the twelve months; and that there is a large number just removed from pauperism who deserve as much sympathy, if not more, than those who actually apply. The great point on which all the Commissioners are agreed is that the State should carefully ascertain its own responsibility in this matter and, where it can, interfere beneficially without damage to the personal respect of those whom it designs to help, and that in future there should be more discrimination in the granting of relief as to the merits of individual cases. This is, no doubt, a duty of great delicacy. It would be very difficult in a work-house, or even in regard to out-door relief, to classify those who are relieved—to give some better quarters and better conditions than others. The great end of all good legislation must be to help men and women to make their own living and work out their own independence. Still, there is room for far more benevolent action on the part of the State towards the poor than has yet been taken, and this investigation, though very imperfect, will help. We have only, in conclusion, to say that one immense factor in the production of pauperism is the element of disease in families, and that in any sound schemes for elevating the social conditions of life provision must be made for more perfectly meeting the medical and nursing wants of the people as well as for improving and purifying their homes.

THE returns from the medical schools in different parts of the country for the present year encourage the hope that the "rush to medicine" is to some extent slackening. It is not well to be too sanguine on this subject, as some of the causes of this slackening—e.g., the circumstances attending the change from a four years' to a five years' curriculum—are to some extent temporary in character, and a few years must elapse before we can feel quite sure that the number of those seeking admission to the medical profession, which all must admit to have been excessive during the last two decades, has undergone any permanent diminution. But some causes of the temporary slackening—e.g., the increasing stringency of the examining boards—are likely to be permanent factors, and we may fairly hope that we

have seen the worst of the overmanning and consequent underpaying of our profession. It is a disagreeable reflection, but a necessary and salutary one, that the honour, dignity, and general well-being of medical men depend upon the numbers of medical practitioners being kept within reasonable limits. If these limits be exceeded—and we take it that in this country and in America they have already been largely exceeded—the inevitable law of supply and demand comes into force, the temptation to undersell their brethren becomes to many irresistible, and the whole profession suffers in dignity. We see what is at present taking place in the city of Cork, where several medical men from a distance have been found willing to accept club practice on terms that the general body of the profession in Cork regard as insufficient. If the professional ranks were not overfull such a thing would have been impossible. It is very important that the public should realise that our protest against the overcrowding of the medical profession is not wholly, or even mainly, a selfish protest. Its main strength is founded on the unquestionable fact that overcrowding is incompatible with high efficiency. If medical men could not look forward to higher rewards than those of a superior clerk or a first-class mechanic it would be obviously absurd to expect them to go through a prolonged and expensive course of preliminary study. Again, if our profession had not substantial rewards to offer men of superior energy and ability it is absolutely certain that such men would carry their powers into more promising fields of human endeavour, and that medical life and the public advantage would proportionately suffer. It is indispensable that there should remain sufficient attractions to youths of superior endowments to induce them to go through a long and most laborious course of study in the hope of some day finding adequate rewards in the medical profession, and those attractions are in the present day in danger of growing steadily less and less, owing to the fact that the young practitioner so constantly finds all fields overstocked and all avenues closed against him.

But the "bitter cry" of the medical world finds only too responsive a wall from the other professions. The overstocked condition of the Bar has been so long notorious that young men without private means hesitate to embrace it as a profession unless conscious of superior powers and special aptitude for forensic work. In recent years the "poverty of the clergy" has become a familiar expression, and we have no doubt that much real distress exists in the clerical ranks. There is, we fear, a real danger of the efficiency and social status of all the professions suffering from the diminution of income consequent upon overcrowding. Our cautious contemporary, the *Spectator*, some time ago published an article of which the burden was that we were within measurable distance of the time when professional incomes would range from £150 to £200 *per annum*. If such a time should ever come it would mean many radical changes in existing things. It would mean that professional training would have to be shortened and cheapened, that the professions would be manned by men of an inferior social grade, and that the general weight and influence of the professions would be to a notable degree less than at present. We cannot think

that such a change would be anything short of a national disaster. If the Church, the Bar, and Medicine be impoverished and degraded, how long will commercial life or the general *morale* of the nation remain at a high level? Not long, we submit, and it is well to recognise that these very material, and even apparently mercenary, considerations have very far-reaching effects.

The remedy, if remedy there is to be, must come in the shape of measures calculated to prevent overcrowding. It is impossible to limit the numbers of those entering the medical profession by any arbitrary rule, but it should not be impossible so to adjust the time and money necessarily spent upon a medical education to the probable rewards to be reaped hereafter, that the number of candidates would not exceed the number of those who might fairly expect to earn a tolerable maintenance. The standard of medical education, both as regards duration, variety of subjects, and stringency of tests, has of late been steadily rising, but we cannot think that it is even now at all too high. The outcry sometimes raised over the poor over-taxed medical student might be not inappropriately answered in some cases by the suggestion that he should transfer his powers to some easier field of labour. Medical life wants more than average men. It wants men of good physique, good *morale*, and at least good intelligence. Such a combination is none too common, and we think the day is past when any youth can be considered good enough to become a medical practitioner. Competition is regulating this, but it is on every ground preferable that the necessary testing should be applied before entrance upon medical life rather than afterwards, when a change can only be effected at the cost of much suffering and loss.

While making the above reflections we are far from thinking that the medical profession presents anything less than the highest attractions even now to a youth of character, energy, and brains. Probably in no profession is a reward proportionate to worth and labour more sure, and if the great prizes are few the blanks, compared with the Bar or the Church, are also few. The aspirant to medicine must look forward to a life of incessant activity and unremitting labour, to heavy responsibility and scanty and uncertain leisure, and to little of the *otium cum dignitate* with advancing years of which the other professions enjoy a large share. But there are great compensations—work that appeals to the sympathetic side of human nature and brings the practitioner into the most intimate relations with his fellows, the gratitude and confidence of patients, a prospect of fair if not large material rewards, and the consciousness of an active, beneficent, and well-spent life. These are great matters, and in our natural and justifiable regrets at the overcrowding and diminished dignity of the medical profession we must not over-colour the picture or forget the many compensations of the lot of a fairly successful practitioner of medicine.

ON a previous occasion¹ we published the recommendations of the London County Council relative to the proposed alteration of the law regulating coroners' inquests. Recently a deputation of the Council appeared before the LORD

CHANCELLOR with a view of urging the pressing necessity for reform both as regards death certification and official investigations into the cause of death. Lord HERSCHELL has taken special interest in the question, as shown by the fact that nineteen years ago he recommended changes which practically form the basis of what the London County Council consider to be not only expedient but necessary reforms. As regards death certification we have on several occasions pointed out the methods by which improvement of the present system could be effected, and these being practically the same as advised by the Council need no further comment from us now. As regards the proposed changes in the law regulating the appointment and duties of coroners, in order to deal with the matter in a short but comprehensive way it may be premised that the main departures from the present system recommended are:—(1) that medical investigators should be appointed who should be attached as officials to the coroners' courts; (2) that London should be divided into districts so as to give approximately an equal amount of work to coroners, and that coroners should be paid by salaries not dependent on the number of inquests held; (3) that coroners' courts should be provided for each district, with a coroner, clerk, inquiry officer, and other necessary officials, as in police courts; and (4) that coroners should have full power to commit on criminal charges and to bind over all witnesses.

Long ago we urged the desirability of appointing official medical investigators and of attaching them to coroners' courts, and it is with satisfaction that we find that our views have been adopted by the Council. With liberal salaries it would be possible to secure the services of thoroughly capable medical men whose functions would be fourfold—viz., (a) to inquire into the causes of all uncertified deaths; (b) to examine the body in all such cases and to make post-mortem examinations where necessary; (c) to report the results to coroners sitting in court; and (d) to give evidence at inquests and act as medical advisers to coroners. If this system were adopted, the obvious results would be to prevent uncertified deaths being registered and to ensure a more efficient method of recognising the causes of death, and thus to remove what may be termed a passive incentive to crime, which the existing statutes are to a great extent powerless to effect. Without detracting from the merits of the profession generally, it may safely be conceded that it is not every medical man who is in a position to investigate the circumstances surrounding many cases of obscure cause of death. The records of inquests where a second post-mortem examination has been found desirable are evidence in complete support of the above contention. But these remarks apply to the employment of specially skilled observers in cases of particular difficulty, and not to the general run of post-mortem examinations, which can be conducted with skill and trustworthiness by the general practitioner. Should the presentments of the County Council receive the sanction of the Legislature it is obvious that the interests of the general body of medical men would be seriously assailed. In the first place, fewer inquests would be held, and thus many fees be lost which now fall to the share of medical men whose services are requisitioned by coroners. The County Council is silent on the matter as to how far the proposed medical investigators would interfere with or supplant

medical men who have attended deceased persons during their fatal illness, or who have been called in subsequently to unexpected deaths. The natural consequences of putting the suggested proposals in force would, in our opinion, deprive the general practitioner of a source of income to which he has looked forward with faith and with a sense of rightful claim. We do not feel called upon at the present juncture to express our opinions upon the equity of the matter, but as a duty to the profession we are compelled to point out the nature and probable extent of the results likely to follow the acceptance by Parliament of the County Council's recommendations. It must also be remembered that the establishment of coroners' courts analagous in area and executive power to police-courts, including the conferring of higher magisterial functions on coroners, and the appointment of medical investigators, part of whose duties would be to sit as medical assessors to coroners, would largely discount the chances of medical men not possessed of a legal qualification attaining coronerships, and the paucity of appointments to such offices would bar many from risking their chances of professional success in other spheres in order to acquire both a medical and legal diploma.

Doubtless, if the proposed amendments and alterations of the law as regards the appointment, jurisdiction, and duties of coroners and the institution of official medical investigators were adopted, the number of inquests would be materially less than at present, and the expense correspondingly diminished. The saving thus effected would go to disburse the charges necessitated by the new regulations. For the rest we most cordially approve of the abolition of franchise coroners and of the present plan of providing deputies for coroners who through illness or other pressing reason are temporarily unable to personally discharge their duties. Deputy coroners are now nominated by the coroners and appointed by them at their expense, subject to the sanction of the Council. The law makes no provision for coroners' deputies, nor does it prescribe the extent to which their services shall be called upon by their superior officers; consequently the deputy may be required to conduct a large share of a coroner's duties without commensurate remuneration.

The important bearing which the scheme of the London County Council has upon the interests of medical men as a body seems curiously enough to have been so far entirely overlooked by the profession. There can be little doubt that if this scheme becomes law it will be made to affect, not only London, but the whole of England.

ROYAL INSTITUTION OF GREAT BRITAIN.—The lectures announced to be delivered at the Royal Institution after Easter should be of considerable interest. On April 23rd, 30th, and May 7th Professor G. Forbes, F.R.S., M.Inst.C.E., will deliver three lectures on Alternating and Interrupted Electric Currents. Four lectures on Thirty Years' Progress in Biological Science will be given by Professor E. Ray Lankester, M.A., LL.D., F.R.S., on May 14th, 21st, 28th, and June 4th Professor Dewar, M.A., LL.D., F.R.S., will deliver four lectures on the Liquefaction of Gases on April 25th, May 2nd, 9th, and 16th; and on May 23rd, 30th, and June 6th Mr. W. Huggins, LL.D., F.R.S., D.C.L., will deliver the Tyndall Lectures on the Instruments and Methods of Spectroscopic Astronomy.

Annotations.

"Ne quid nīmls."

THE DANGERS OF ELECTRIC MAINS.

WE have received a copy of the return made to an order of the House of Commons containing the report of inquiries, held by Major Cardew by direction of the Board of Trade, into the circumstances attending certain accidents in connexion with the electric light mains in the City and the Euston-road. In regard to the explosion in Budge-row, Cannon-street, Major Cardew considers that the Electric Light Company and their officers and employes were to blame for want of judgment, carelessness, and inattention to the regulations imposed by the Board of Trade. To begin with, the inexcusable blunder was committed of charging one main under the impression that it was another, the consequences of which (the pressure being enormous) might easily have proved fatal. Then it appears that there was no provision made by which mains when subjected to an excessive current could be cut out of the circuit automatically. Again, the use of indicators to show the disturbance of potentials with regard to the earth and the rush of current through the mains affected might have prevented a breakdown, or at least shortened the duration of such dangerous conditions. Then come the important questions as to why it was that the street surface could become so dangerously charged in consequence of any defect in the mains—as in the case of Budge-row—to kill a horse; as to why the high-pressure main in the street box was not enclosed in strong metal casing efficiently connected to the earth in accordance with the regulations of the Board of Trade under the Electric Lighting Acts, 1882 and 1883; and, lastly, as to why the accumulation of gas to which the company attributes the explosion was allowed to take place, when they themselves proved gas to exist in a neighbouring street box. These points are dealt with at some length in the report, and the proper preventive lines are suggested, which, if thoroughly carried out, should remove any farther cause of anxiety as regards the public safety. Referring to the St. Pancras explosion, Major Cardew, in view of the evidence placed before him and of his own investigations, is of the opinion that the explosions were caused by the firing of a mixture of coal gas and air by an electric spark. It appears that some days after the explosion a four-inch gas main was found to be leaking in a position about eighty yards from the electric light conduit. There is reason to believe that this gas, assisted by the small amount of heat produced by the current in the electric mains, would percolate along the channels of both mains, which are contiguous, into the boxes. The occurrence of an electric spark was probably, Major Cardew thinks, a result of the formation of a salt incrustation on the insulators. This incrustation probably acts to some extent, it is pointed out, as a conductor, and if a piece breaks away a small spark would very likely be caused. The vestry of St. Pancras are enjoined to lose no time in removing the two existing causes of danger just indicated, and steps should immediately be taken, as was pointed out in THE LANCET of March 9th, to provide a thorough system of ventilation or means for the immediate escape of gas from their conduits and street boxes, and they should reduce the empty space available for accumulation of gas in their street boxes as far as possible, and should carefully guard against the dangerous formation of an incrustation of salts on the insulators of the negative main by frequent inspection and by protecting the insulators against drip from the condensation of moisture on the iron lids of the street boxes. What has become of the sodium theory said to have

been put forward by Major Cardew, to which we alluded in the article just referred to? In the present report we find no mention of it.

"A CURE FOR CANCER."

CERTAIN details published respecting the discovery by a Bernardine monk in Leicestershire of a reported "cancer cure" recall the gropings of medical intelligence in the Dark Ages. It is not a little interesting to see this kind-hearted man with no prospect of personal gain, but, alas, with as little knowledge of the character of cancer, using his herbal decoctions with honest zeal in efforts to soothe his suffering neighbours. The evident intention is wholly commendable. Would that we could say as much for its effects. Brother Philip on one occasion last June bruised his hand. A wound which followed the accident healed slowly, but it did heal at last under the application of certain herbs which he considered "would together heal any wound." He believed that his wound was a cancer, and the thought struck him that perhaps he had found a cure for this disease. *O sanota simplicitas!* Could anything be more mystic or more misty than the relation here suggested between premisses unexplained and a conclusion all assumed? Brother Philip had occasion soon after this to treat a woman aged eighty-three years for what was described by her medical attendant as "cancer." In four months' time this had nearly healed. The question of diagnosis in this case remains an open one. It is probable that fuller details would expose its fallacy, but whether this be the case or not, the result claimed for the new empirical method is in the circumstances not impossible. Unfortunately by this assertion we destroy the reputed efficacy of the new remedy. Cancers in the aged, as is well known, sometimes progress but slowly, and even at times appear to undergo spontaneous absorption, and this quite independently of any local applications. No credence, therefore, can be accorded to the professed virtues of Brother Philip's decoctions. His medicaments are commendable only in their intention, the friendly motive of their introducer. They are open to the very serious objection that they profess far more than can be believed of them by any properly instructed person. As "cancer cures" they may safely be dismissed to the limbo of all such unfounded inventions, and those who may be tempted to employ them should remember that by so doing they lose time which, if not early used for other and more effective surgical treatment, will cost them their sole chance of recovery.

PULEX IRRITANS.

A CORRESPONDENT, writing on behalf of the staff and habitants of the institution to which he belongs, begs us to state some means whereby a plague of fleas from which they are suffering may be put an end to. Such a request is not an unusual one, and on several occasions correspondents have suggested remedies. As far as we know, the best and indeed only effectual means of getting rid of these pests is by thorough and systematic cleaning. *Pulex irritans* goes through its various stages from the egg to the perfect insect in a period of about a month, and the first thing to do, therefore, is to thoroughly cleanse all articles likely to form a nidus for the eggs at periods within a month or before the eggs burst. Furs, woollen garments, mattresses, pillows, and all such things, and the various folds and pleats in our clothes, are frequently chosen as suitable places for the deposit of eggs. While linen materials generally receive frequent and thorough cleansing, the articles we have just mentioned are often but imperfectly cleansed, and herein, in many cases, lies the unsuspected cause of the plague. As long as the plague lasts blankets should be washed at least once a fortnight and subjected to

a temperature—either by steam or by some other means—sufficiently high to kill the ova. Old pillows should be destroyed or subjected to heat in the same way, and carpets, rugs, curtains, and clothes—in fact, anything likely to form a harbour for the pest—should receive similar attention. Floors should be washed at least once a fortnight with salt and water (about a handful to a pint),—a strong decoction of laurel leaves, it is said, will answer the same purpose. Several plants, from their power of destroying or driving away the pest, have received the name of “*flæbane*,” but their efficacy is perhaps more supposed than real. Some years ago a correspondent who had travelled a great deal in England and on the Continent, whose experience of hotels and inns included those of Austria and Italy, advocated in our columns the use of the common English lavender kept with clothes or in beds. Good lavender water or a solution of the oil of lavender in spirit frequently sprinkled on beds and clothing should have the same effect. Paraffin oil is said to drive away these insects if sprinkled freely, but the great objection to this is of course the smell. If before retiring for the night the body be sponged with weak vinegar and water pulex irritans will often cease from troubling. To allay the irritation caused by the bite sal volatile or salt and water is generally efficacious.

MISTAKEN LIBERALITY.

It is not often that a purchaser has to complain that the material supplied is “too strong.” Licensed victuallers and refreshment contractors might be tempted to greet such complaint as sarcastic chaff, though purveyors of certain kinds of cheese might not be surprised. Cheese, however, is not yet included in the Pharmacopœia, but diluted acetic acid finds a place therein, and an unlucky druggist who sold a specimen of more than twice the pharmacopœial strength has been called to account. The case is still *sub judice*, but in the course of argument the intention of the Food and Drugs Act was called into question. It was suggested that the intention was to prevent fraud by dilution of such substances as milk and beer. Whatever the Act may mean there is no doubt that one of the primary ideas of the Pharmacopœia is to ensure uniformity, and this sword cuts both ways. It is unlikely that preparations of opium should be made containing more than the prescribed alkaloidal strength, but the danger of a benevolent desire to give more than is expected is sufficiently obvious in such a case. With diluted acetic acid the probability of danger depends upon the mode of employment, and with this the Pharmacopœia is not concerned. The judgment will be awaited with interest, since it is surely important to medical men to obtain drugs of constant strength, otherwise unexpected therapeutic, or rather toxic, results may be anticipated.

THE NORMAL PRÆCORDIA IN CHILDHOOD.

Dr. WHITNEY¹ publishes observations which he has made on the normal præcordia of childhood. An accurate diagnosis of heart disease naturally depends considerably on the accurate mapping out of the limits of the cardiac dulness. Dr. Whitney, from the study of a large number of cases, has arrived at the following conclusions: 1. In children, until the beginning of the sixth year, the outline of dulness of the heart in its normal condition has practically the same limits as in the adult—namely, above and to the left, a curved line extending from the junction of the third rib and the sternum outward and downward to the apex of the heart in the fourth interspace, a little internal to the mammary line; the right border, a perpendicular line corresponding very nearly with the left border of the sternum. The lower half of the sternum is therefore of the same resonance as is obtained over the upper half in children under six years of

age. 2. From the fifth to the ninth year the præcordial dulness varies in different cases. A considerable majority of children whose ages vary between these years have an area of cardiac dulness which does not differ from that found in infancy and in adult life. At five years, in all the cases which Dr. Whitney examined, the præcordial dulness was the same as that found in younger children. But at six years there were two cases of the area found in infants to one in which the area was enlarged, and at seven years of age there was about an equal number of each. At eight the proportions had changed, and there were three which were enlarged to two which preserved the usual area. At the age of nine the infantile condition had completely disappeared. The conclusion to be drawn from these statements is that not much importance can be attached to variations of the cardiac dulness in children between the ages of five and nine. 3. In children over eight and under the usual age of puberty the normal limits of the præcordia are always found to differ considerably from those of infants and of adult life. The upper border is generally higher. It is often as high as the second interspace, and occasionally as high as the second rib. The apex is usually a quarter to half an inch outside the mammary line. The right border, instead of being a perpendicular line along the left edge of the sternum, is a curved one which meets the line of liver dulness at a point outside of the right sternal edge one and a quarter to one and a half inches to the right of the median line. The outline is somewhat similar to that of a pericardial effusion.

NEITHER FOOD NOR DRUG.

THERE are certain articles of general consumption which, strictly speaking, are neither food nor drugs, the quality and character of which, nevertheless, it is desirable should be just as much beyond reproach as the indispensable members of our common dietary. Again and again the question arises in legal proceedings instituted under the Food and Drugs Act as to whether the article called into question is a drug or food, and frequently the prosecution fails because the article cannot be regarded as serving the purpose of either. A notorious example of this sort is the case of alum in baking-powder, which has been ruled in the High Courts as not a food within the meaning of the Act. On the same line of reasoning we might also exclude such things as condiments from its operations, and many other commodities about the purity of which, though neither strictly food nor drugs, it is equally desirable there should be no question. The time has come when many substances now outside the meaning of the Act, not being food or drugs in the common acceptance of the words, but which are consumed partially or totally in some way or another, should be made to conform to the Act's requirements of standard and purity. Putting aside the temptation to practise fraud in regard to these articles, the public have no security, it seems to us, against the use in them of possibly injurious substances. Last week an appeal was made in the Queen's Bench Division on a decision of certain justices at Chesterfield who had refused to convict the respondent of an offence under the Food and Drugs Act. It appears that the appellant purchased of the defendant three sticks of chewing gum, and each was labeled “Cloves, for chewing only, and not to be eaten.” A stick was submitted to the county analyst, who reported that it contained 35 per cent. of paraffin wax, that the wax was insoluble, and that if a portion of it was swallowed it would be injurious to health. In the end Mr. Justice Cave said he was of opinion that the appeal should be dismissed. The magistrates had found that the article in question was not an article of food, and he could not say they were wrong. Mr. Justice Wright concurred. The article in question, it is true, was only intended for chewing,

¹ Archives of Pediatrics, November, 1894.

and not swallowing, and it is interesting to opine what the decision would have been if the foreign substance found had proved to be even more injurious than paraffin wax. The probability, however, of swallowing this hybrid jujube is extreme, and the risk involved by children, for instance, who appear to be the biggest consumers, is serious. Paraffin wax is a refractory, inert substance, which probably passes through the system for the most part unchanged, while it doubtless hinders the digestive functions and would tend to obstruct freedom of passage. The public have a right, we contend, to demand an article of purity and free from objection, be it food, drug, or other thing destined for consumption in one way or another. The practice of chewing tobacco is detestable and objectionable enough, but even for this purpose tobacco and nothing but tobacco should be supplied. These are subjects which are engaging the attention of the Food Products Adulteration Committee now sitting, and we trust they will see their way to recommend an extension of the scope of the Acts so as to include many articles of consumption which are not necessarily food or drugs, the sale of which should all the same be under some control.

PARISH HOSPITALITY.

It is not to be expected that the demands of a luxurious taste should be considered in making arrangements for the management of parish hospitals and asylums. If the claims of humanity be met the ratepayer may feel that he has done his duty. These claims, however, constitute the irreducible minimum immediately below which is the freezing-point of charity. In some institutions it would appear as if the temperature of social usage never rises above, if, indeed, it reaches, this level. Trained nurses are needed, but their place is filled by ignorant and superannuated paupers; stimulants are called for, and, as constantly happens, they are dispensed by the thimbleful. Visiting friends are treated with scant courtesy. The case of these latter has lately been taken up by the Mile End board of guardians, who have very properly condemned an absurd custom still practised at Claybury Asylum. At 5.30 A.M. the inmates of this establishment must get up for the day. Visitors who may have passed the night with dying relatives are at the same hour dismissed from the building to return, if they choose, after the breakfast hour. Anyone can appreciate the discomfort implied in this arrangement, carried out as it is under under all conditions of weather and season. A waiting-room could no doubt be very easily provided and warmed with a stove or fire at no great cost. Nor should there be any difficulty in providing at the breakfast hour some simple refreshment for any visitors willing to pay a trifle for it. We are pleased to note that the Mile End guardians are disposed to institute a reform in the present inhospitable system, and we would commend their action to the notice of the parochial authorities elsewhere, who may be conversant with customs of an equally rigorous character.

OPTIC NEURITIS FOLLOWING OZÆNA.

In a recent number of the *Annales d'Oculistique* Dr. D. E. Sulzer has an article on this curious and interesting condition. He says that he has not been able to recognise any symptom of abscess of a sinus in the two cases complicated with optic neuritis which he himself has observed. These cases are noteworthy on account of the long duration of the symptoms. The first patient, thirty-four years of age, had been subject to ozæna from early youth; seventeen years before he came under Dr. Sulzer's observation he had had an operation performed on the nose, and had ever since freely irrigated it with boracic acid in order to mitigate the fetid odour. Lately, however, these precautions had been neglected. The turbinated bones on the left side were small; those on the right, as well as the posterior art of the septum, were

absent, having been removed at the operation referred to. For ten or fifteen days before he had consulted Dr. Sulzer he had observed an obscurely veiled portion situated at the lower and inner side of the left visual field. In this portion objects were seen indistinctly and with fringed borders. Examination with the perimeter revealed a large irregular scotoma in the left visual field. With the ophthalmoscope the papilla of the right optic nerve was found red and swollen, the redness and swelling being almost confined to the superior part of the papilla. At the nasal side a small hæmorrhage was visible. No affection of the sinuses was found, and no abundant discharge from the nose had at any time been observed. During the next two years no further symptoms developed, but amelioration of the ocular condition proceeded *pari passu* with the improved condition of the nose. The lacuna in the visual field disappeared entirely after three months' treatment, but the ophthalmoscopic changes have never entirely ceased to be visible. The second case was that of a woman aged twenty-seven whose vision had failed for several years. Central vision was found to be considerably reduced and the lower halves of the visual fields were almost completely absent; ophthalmoscopic examination revealed redness and swelling with obscuration of the margin of the disc in the upper halves. The changes were more marked in the left than in the right disc. Ozæna had existed since early youth, and the left nasal fossa, especially the middle turbinated bone, was covered with yellow crusts emitting an intensely offensive odour. Treatment of the nose with warm boracic acid irrigations soon led to great amelioration not only of the nasal trouble but also of the ocular. The vision improved, the swelling of the discs subsided, and within a very short time the ophthalmoscopic changes had almost disappeared. Dr. Sulzer in conclusion briefly discusses the etiology of the neuritis in these cases, but, as he remarks, the facts observed do not yet justify him in formulating any definite theory.

PRELIMINARY EDUCATION FOR MEDICAL STUDENTS.

A CIRCULAR letter, signed by the Deans of most of the London medical schools, has been sent to the headmasters of the public, grammar, and intermediate schools in England and Wales, calling their attention to the advantages of matriculating at the University of London in the case of any pupil who intends to study medicine at a London medical school. This is the outcome of the new regulations by which a five years course is now as necessary for a diploma as for a medical degree, and consequently the latter will be more frequently taken than under the old regulations. The advice to a pupil to pass his preliminary examination at the University of London is admirable, but it must be remembered that many who will become medical students cannot attain to this standard while many headmasters, for obvious and valid reasons, object to instruct their pupils with a view to the examination. Either a boy must have special tuition, or a matriculation class must be in regular work in his school, and this is not likely to be the case in the principal public schools of England. The range of subjects is so large that no boy can master them in the ordinary routine of school life, and in few schools can a proper training in mechanics, chemistry, physics, or botany be obtained. In 1886 a subcommittee of Convocation recommended considerable alterations in the syllabus for this examination, but practically the Senate has left the examination as it then stood. In the report of that subcommittee will be found expressions of great dissatisfaction from many of our most eminent school authorities, and it is but little likely that they will change their present systems of teaching with a view to meeting the tests whose desirability they have denounced. The fact

is that the matriculation examination aims at two objects, which are incompatible. It is looked on by many as a certificate of proficiency for boys leaving school, whilst it is also the entrance examination for the University degrees. So far as it fulfils the former purpose, it must fail as a proper commencement to the latter. It would be one of the first duties of a teaching university to arrange a proper examination to serve as the portal to its degrees.

ST. GEORGE'S HOSPITAL.

DR. PATRICK MANSON has been appointed Lecturer on Tropical Diseases in the St. George's Hospital Medical School. Dr. Minson will give a course of some twenty lectures on the principal diseases peculiar to the tropics and Eastern Asia during the summer session of each year, commencing this year early in June. They will be illustrated by demonstrations of living patients and of microscopic objects shown by means of the electric lantern, with which the St. George's lecture rooms have lately been fitted. The lectures will be especially adapted to the needs of medical men preparing for service in the tropics or the East, and admission to them will not be limited to students of the St. George's School. This is, we believe, the first provision made by any English school for special instruction in this important subject.

THE HEALTH OF LORD ROSEBERRY.

WE are happy to announce that Lord Rosebery's health continues to improve, though the duration of his period of convalescence speaks to the severity of his attack and the wearing nature of the chief symptom—insomnia. He has gained in strength during the week, and in general tone, and has enjoyed better nights; but, as can be readily believed by those who have watched the politics of the last few days and have noted the acrimonious spirit that has crept into them, public affairs have made great demands upon him and have undoubtedly retarded him in his progress to health. The Cabinet Council held on Saturday last at Downing-street was unusually protracted, and as a result of the anxiety and fatigue the Premier passed a bad night. He has not yet left The Dardans, partly because the unsettled state of the weather did not promise him a pleasanter sojourn at Walmer, but chiefly because the proximity of his Epsom house to London renders it easy for him to see his colleagues and personally assist in their deliberations.

THE PREVENTION OF WINDOW-CLEANING ACCIDENTS.

ACCORDING to the report of the Registrar-General the number of fatal falls from the window in England alone is eighty per annum, but notwithstanding this fact little has been done either on the part of the Government or on the part of house-owners to take means to lessen this unnecessary mortality. In 1892 the corporation of Glasgow passed a by-law enacting that in dwelling-houses all window-sashes above the ground floor should be hinged or constructed so as to admit of the outside of the windows being cleaned from the inside of the apartment; and we believe that an old Act, passed in 1847 and applying to English boroughs, made it an indictable offence to allow anyone to stand outside a window, with a fine of 40s. payable by the occupier. But this Act is undoubtedly a dead letter in the country, and would anyhow be impracticable in a large city like London. The proper remedy obviously lies in the fitting of the window itself. If this can be so constructed that the operation of cleaning can be performed from the inside, whilst the framework is both air- and water-tight, the safety of the cleaner is assured, but before any such innovation can become popular among those who have grown up among sashes, and

are returning to casements, it must be made clear that the new invention does not lose in comfort for its user what it may gain in safety for his servants. The framework must be air-tight and water-tight, and the general effect must be good to look at and obtained at a reasonable cost. These and many other advantages are possessed by the National Accident Prevention Window, which we have had an opportunity of examining at the Builders' Exhibition held this week at the Agricultural Hall, London. The window, which has the appearance of an ordinary window, consists of top and bottom sashes, each of which can be drawn inwards and attached to a stay bar while being cleaned, the top sash drawing down so as to render it unnecessary for the cleaner to use steps or to raise himself above the level of the floor. Cleaning is thus rendered perfectly easy and the risk of loss of life is obviated. At the same time the peculiar construction of the sash and frame entirely prevents draughts. When necessary for the admission of a large body of air or for the entrance of cumbersome articles of furniture, the window can be lifted out; and reglazing can be done inside the room with perfect safety. The cost of fitting this window to existing frames varies from 17s. 6d. to £1, and a new window and frame in this style costs but 17s. 6d. more than the fitting of an old-fashioned window. The same firm exhibit a window adapted to hospitals, which, while possessing the same advantages as those we have just alluded to, has in addition a hopper transom light, with glazed wooden cheeks and a ready means of drawing the fanlight inwards for cleaning. A casement window is also shown which opens inwards and outwards, and is perfectly watertight. We are glad to note that these windows are now the accepted model in building new Board schools in London.

THE BACTERIOLOGICAL TEST OF THE PURITY OF WATER.

WE desire to call attention to the excellent scientific work of a practical and useful character that is at present being carried on in India, thanks to the labours of Professor Hankin, the chemical examiner and bacteriologist to the Government of the North-West Provinces and Oudh. Professor Hankin, who is a Fellow of St. John's College, Cambridge, is by his training eminently qualified for the work he has undertaken and is prosecuting in India. He has just written and published a short pamphlet for the use of municipal engineers and others interested in providing water for drinking purposes, in which his aim has been to explain the process of testing for microbes present in water to those who wish to carry out this process for themselves. He states his conviction that the time has come for substituting the simpler, cheaper, and more reliable method of "microbe counting" for the cumbersome and expensive one of testing municipal water chemically, and he considers that the former method should be relied on to learn whether municipal filter beds are performing their functions properly. This opinion is mainly based on the observations and evidence of Prof. Koch in his paper "Wasserfiltration und Cholera," which was translated and published as an appendix to the report of the medical officer to the Local Government Board for 1893. Of course, the great value of the chemical test for other purposes is not questioned; but cases have been known, says Professor Hankin, in which a breakdown of filter beds that caused an epidemic was detected by means of the bacteriological test when the chemical test failed to afford any indication that anything was wrong with the water. The little pamphlet under notice contains much interesting information regarding the bacteriology of the waters of Indian rivers as compared with those of Europe; the process of filtration and the *modus operandi* of sand filtration; the municipal filter beds, filter-tank wells, and water-supplies of India, and the accidents to

which they are exposed; together with a description of the method and apparatus necessary to carry out the bacteriological examination of water.

THE MALE NURSES' (TEMPERANCE) COÖPERATION.

WE have received a report of the first year's working of this association, from which we learn that the average earnings of each man have been at the rate of £97 2s. 5d. per annum after paying all expenses. This is certainly a gratifying result, and we congratulate the association upon it. The old-fashioned drinking female nurse is quite extinct, but, as the report says, a prejudice has hitherto existed against male nurses owing to the number of drunken and doubtful characters calling themselves by that name. This prejudice the association in question has set itself to overcome, and we trust their efforts will meet with success. The offices of the association are at 8, Great Marylebone-street, Portland-place, W., and all information will be supplied by the secretary, Mr. F. Rouse.

THE LIFE-SAVING SOCIETY.

It is only within recent years that swimming—most ancient of exercises—has received the attention which it deserves and that much encouragement has been given to the art, from the life-saving point of view as well as from the athletic. With this idea before it the Life-Saving Society was formed, and its beneficial objects, which are now known almost throughout the world, have met with much encouragement. The annual report of the society, which has just been issued, is a most satisfactory record of progress. It gives us great pleasure to note the number of medical men throughout the kingdom who have taken an active interest in the society, and to whom the executive tender their hearty thanks. The public lectures and demonstrations of rescue, resuscitation, and release from the clutch of a drowning person have been well attended, and the number of clubs that have been induced to start life-saving classes shows a marked increase. It is needless to say that such work cannot be carried on efficiently without substantial pecuniary aid, and such a society should not ask in vain for public support. On the necessity and importance of the art of swimming being taught as part of the ordinary school education we have insisted in these columns more than once, and all efforts to establish new swimming baths have always met with our warmest support. In this connexion we are pleased to note that at last there is some prospect of a swimming bath being built for the City of London. The City of London Swimming Association, which with its affiliated clubs boasts a membership of over 3000, has long agitated for a home, and it is now stated that the Commissioners of Sewers are considering sites and plans for this purpose.

A MATTER OF ETIQUETTE.

A QUESTION has recently come before the vestry of St. George's, Southwark, which shows how difficult it may be for laymen to understand the ordinary rules of courtesy and ethics which govern members of the medical profession. It appears that Dr. Waldo, the medical officer of health, agreed, under the terms of his appointment, "to attend, if required, the employes of the vestry during illness." We presume that this meant if the employes wanted him instead of their usual medical attendant. At a meeting of the vestry, held on the 12th ult., Dr. Waldo was instructed to attend the sick employes and report upon their condition, and at the vestry meeting held on the 26th ult. he reported that he had done so, and that he had explained to the clerk that the usual custom was for the medical man in charge of the case to be consulted before another medical man came upon

the scene, and to get a double fee; he had also asked the clerk if he could guarantee this fee to the medical men on behalf of the vestry. The chairman said the object of the resolution of the 12th was to prevent malingering, and another vestryman said he thought Dr. Waldo could pay an occasional visit without a consultation. Dr. Waldo thereupon explained the etiquette of the matter, saying he could not say whether a man was malingering or not without making an examination. To this a Mr. Bray remarked that it was never intended that the medical man should diagnose the case, for he thought that the practitioner could tell by the colour of a man's face whether he were ill or not! Eventually the matter was referred to the Works Committee after Mr. Barr had said that the proposal of the vestry placed their medical officer in the position of passing a vote of censure on other medical men. Mr. Barr's remark seems to us to comprise the whole gist of the matter, and we are glad to see that at least one member of the vestry was able to view things in this light. We shall be curious to learn the result of the Works Committee's deliberations, and can only hope that they will stand by Dr. Waldo in the honourable position he has taken.

THE LONDON HOSPITAL MEDICAL COLLEGE.

A STAINED-GLASS window containing the coats of arms or crests of past or consulting members of the staff of the London Hospital has just been erected in the Library of the London Hospital Medical College. It has long been desired to perpetuate in some manner the names of those who worked and taught for so many years both in the Hospital and College, and it was recently decided to adopt this form of memorial. The window just erected contains thirty-two shields on which are displayed the armorial bearings of past or consulting members of the staff, including those of Dr. John Andree, first physician, and Mr. John Harrison, the first surgeon, appointed in 1740. There are also the coats of arms of Sir William Blizard, Sir Andrew Clark, and Messrs. Richard Clement Headington, John Goldyer Andrews, James Luke, Thomas Blizard Curling, and Jonathan Hutchinson, all at one time or another Presidents of the Royal Colleges of Physicians or Surgeons, as well as other distinguished members of the medical profession who were on the staff of the London Hospital. It is hoped in time to add the armorial bearings of many others whose descendants at the moment have not been traced, and any information with reference to former members of the staff whose names do not appear in the present window will be gladly received by the Warden of the College, who will be pleased to show the window to all who may be interested.

FROUD v. SNELL.

WE recently commented upon a proposition made by a correspondent with regard to limiting the opportunities afforded to phthisical subjects for marriage, and now the question has appeared in the unromantic atmosphere of the Law Courts. Dr. S. H. Snell, a medical practitioner, had promised to marry a Miss Froud, but a month or so before the intended date of the marriage the defendant discovered that Miss Froud's mother had died from "phthisis meningitis," and thereupon broke off the engagement. The result of this was that on April 2nd, in the Queen's Bench Division, a jury found a verdict for Miss Froud for breach of promise and awarded her £1000. Mr. Justice Hawkins refusing to stay execution. The plaintiff's counsel tried to bring out the point that the defendant was influenced in his actions by the fact that Miss Froud was the daughter of a butcher, while he was the son of a costumer, and therefore higher in the social scale; but this allegation was not supported by any convincing evidence. Dr. Snell's point was that he did not care to

have the responsibility of being the means of possibly bringing children into the world who would suffer from the hereditary taint of phthisis. Undoubtedly a man who marries when he has either a phthisical history himself or selects as his wife one labouring under the same disability does take upon himself a heavy responsibility, and Dr. Snell's views on that question cannot be too highly commended. Our sympathy with him would, however, have been greater (indeed, would probably not have been needed) had he taken the trouble to ascertain particulars of the lady's family history before "proposing" to her and had he refrained from imputing fraud to the plaintiff with respect to the cause of her mother's death. She was only eleven years old when her mother died and so probably would know nothing of the matter.

NOTIFICATION OF TYPHOID FEVER.

AN important case in regard to notification is reported in the *Yorkshire Evening Post* affecting the question whether it is the duty of more than one medical man to notify. A case of typhoid fever was attended at Cullingworth by Mr. Jackson of Denholme, who notified. Later Mr. Beckett was called in, and apparently without inquiring whether the case had been already notified, also notified. For this second notification the District Council refused to pay, on the ground that the case had been already notified. The magistrate took the view that Mr. Beckett should have inquired, and on ascertaining that his predecessor in attendance had notified should have desisted from further notification; but he deferred judgment. We are clear that it was Mr. Beckett's duty to notify in accordance with the words of the Act: "Every medical practitioner must notify forthwith." This point we have already dealt with in a recent series of articles entitled "Difficulties under the Infectious Disease (Notification) Act," which has been reprinted in pamphlet form.

DIPHTHERIA IN LONDON.

THE mortality from diphtheria has again risen, the figures for last week being 6 above the corrected average, and in all 31, as compared with 34, 27, and 24 in the three preceding weeks. All the 31 were persons under twenty years of age; 6 of these belonged to Greenwich, 3 each to Camberwell and Poplar, and 2 each to Battersea, St. Pancras, and Westminster sanitary areas. The admissions to hospital last week were 67 in number, and compare with 55, 61, and 64 in the preceding three weeks; the number of patients remaining in hospital, which had varied but very slightly for three weeks, fell 20. The number of admissions, however, gives but very little idea of how the disease really stands, as the admissions, last week for example, were only some 60 per cent. of the cases heard of in London. It is true that the cases of March show a large drop compared with those of January of this year, but they also show a heavy rise on the total for February. Roughly, we have for the three months of the past quarter 800, 425, and 500 cases to consider. In the same months of last year the respective figures were 1050, 800, and 750, and the quarterly total for last year works out at some 2600, against 1740 for the current year. Judged by case mortality the comparison for the two quarters is as follows, 1894 being in each instance first named:—January, 28.0 and 23.0; February, 27.0 and 23.4; March, 29.2 and 23.0; and for the three months, 28.0 and 24.5 per cent. So, speaking generally, the present is a milder epidemic, and also a more limited one in point of numbers, although it appears of late to be recrudescing to some extent.

DR. ARTHUR GAMGEE, F.R.S., of Lausanne, is, we are glad to say, recovering from the serious attack of double pneumonia consecutive to influenza from which he has lately suffered.

ON April 1st there started for Massowah *en route* to the Colonia Eritrea (Red Sea Colony) a first relay of the staff and *matériel* of the Italian Red Cross Society destined for active duty in the frontier warfare in which the army of occupation, native and European, has been engaged for ten years. It consists of a hospital fitted up with fifty beds, with a transport service of mules and a carefully selected body of physicians, surgeons, nurses, and attendants. A full account of the initiative thus taken by the Società della Croce Rossa Italiana and of its probable scene of operations was given in THE LANCET of Feb. 23rd, 1895.

THE University of Aberdeen has bestowed the degree of LL.D. *honoris causa* upon three distinguished members of the profession:—Sir J. Russell Reynolds, Bart., F.R.S., President of the Royal College of Physicians, London; Surgeon-Colonel Robert Harvey, D.S.O., Honorary Surgeon to the Viceroy of India and the President of the recent Congress of Medicine in India; and Sir William McGregor, M.D., K.C.M.G., the newly appointed Lieutenant-Governor of British New Guinea. Sir William McGregor's appointment was gazetted last week; he has been for seven years Administrator of British New Guinea.

OUR Durham correspondent calls the attention of the medical graduates of the University of Durham to the fact that the biennial prize in surgery, due to the beneficence of the late Professor Heath, will be awarded next year. The Heath Scholarship, being the interest of £4000 accumulating for two years, is one of the most valuable surgical prizes in the kingdom, and we feel confident that the trustees will have before them by next March an assortment of careful contributions to surgical science between which to discriminate.

MR. CHARLES SCOTT SHERRINGTON, M.A., M.D. Cantab., F.R.S., Professor-Superintendent of the Brown Institution and Lecturer on Physiology at St. Thomas's Hospital Medical School, has been appointed Holt Professor of Physiology in University College, Liverpool, in the place of Professor Francis Gotch, F.R.S., the new Waynflete Professor of Physiology in the University of Oxford.

THE annual meeting of the North London Medical and Chirurgical Society will be held on Thursday, the 11th inst., at the Great Northern Central Hospital, Holloway-road, at 9 P.M. The President, Dr. Glover, will deliver an address on the Profession—its Place and Progress.

THE President of the Local Government Board has appointed Major-General A. de Courcy Scott to inquire into the complaints that are being generally made against the working of certain of the metropolitan water companies.

DR. WILLIAM MARCET, F.R.S., will deliver the Croonian Lectures at the Royal College of Physicians of London on June 18th, 20th, 25th, and 27th. The subject of the four lectures is the Respiration of Man.

MR. ANDREW CLARK, F.R.C.S., Assistant Surgeon to the Middlesex Hospital, has been elected a full surgeon to the hospital, filling the vacancy caused by the death of Mr. J. W. Hulke.

MEDICAL MAGISTRATES.—Mr. W. C. Faulkner, M.B. Edin., of Rockhampton; Mr. M. W. C. Perceval, L.K.Q.C.P. Irek., of Isistord; Mr. W. E. Roth, L.R.C.P. Lond., M.R.C.S., of Boulia; and Mr. D. W. B. Wilkie, M.B. Melb., M.R.C.S. Eng., of Gayndah, have been appointed Justices of the Peace in Queensland.

PROFESSOR KOCH ON WATER-SUPPLY AND CHOLERA.

PROFESSOR KOCH's recent work on this subject has been translated into English by Mr. George Duncan, M.A., and is entitled: "Professor Koch on the Bacteriological Diagnosis of Cholera, Water Filtration and Cholera, and the Cholera in Germany during the Winter of 1892-93." It is published in Edinburgh by David Douglas and has a few words of preface by Professor W. T. Gairdner, M.D., LL.D., F.R.S. So far as it deals with bacteriology, every line will be read with the interest and respect due to certainly one of the greatest among the bacteriologists of all nations; but when Professor Koch deals with cholera in relation to the water theory he opens out controversial ground. No one can accuse *THE LANCET* of not having repeatedly and forcibly dwelt upon the important connexion which exists between outbreaks of cholera and contaminated or impure sources of water-supply, and this at a time, too, when the subject had not attracted anything like the attention that it has at present. But there is, nevertheless, a danger of people forgetting that contaminated water has not yet been demonstrated to be the sole and exclusive cause of cholera. It is, no doubt, a most important—probably the most important—point on which to focus attention in times of cholera prevalence, but it is not everything, and to direct and limit our efforts in public sanitation in this direction only is to curtail our powers, and to court may be disappointment and failure in the future. Speaking of the influence of water in the spread of cholera, it is right, however, to point out that Professor Koch says: "Some, misled by isolated observations of a specially surprising nature, have gone decidedly too far in this direction, and declared water to be the exclusive bearer of the germ of cholera. To these the designation of 'water fanatics' or 'water theorists,' which has been much used of late, may not quite unjustly be applied. That I do not belong to this class of cholera investigators will be admitted at once by everyone who knows what I have said and written about cholera. I have always said that, according to experience hitherto gained, direct transmission from person to person is possible, but to all appearance not very frequent; that, on the other hand, indirect transmissions by many bearers of the germ of cholera play the principal part in the real epidemics and mass outbreaks of that disease, and that among these bearers water is one of the most important. I have further endeavoured to show by examples that, under certain conditions, water has really played the part ascribed to it. Beyond that, however, I have never, as far as I know, expressed an opinion as to the extent to which this factor is to be regarded as effective. Nor has it been possible hitherto to arrive at a definite judgment on this subject, because investigations of the relations of cholera to water have almost always been undertaken from a one-sided point of view and are therefore generally open to objection. Why, under such circumstances, attempts have been made to stamp me, of all people, as a 'drinking-water fanatic,' I do not clearly understand. It seems almost as if the purpose were to attribute to me by hook or by crook opinions which it is easy to refute."

These are words which we gladly reproduce, though unfortunately they are not quite borne out by the context of the book. On the very same page, speaking of Hamburg, Altona, and Wandsbeck, Professor Koch says: "These three places, which immediately border on one another, and, strictly speaking, form one single city, do not essentially differ from one another except in the one respect that they are differently supplied with water." It would surely be difficult to find a more "one-sided point of view" than is implied by this assertion. Whatever may be the point of view of a bacteriologist, to the sanitarian great and fundamental differences exist between the places mentioned. A great portion of Altona stands high on a dry rock and is easily drained; the part of Hamburg which was most severely affected by the cholera epidemic is on low-lying marshy soil. Indeed, so unmindful is Professor Koch of sanitary conditions that he even caps the above sentence by saying, a few pages further on, that "Hamburg is one of the best drained cities of the world." Considering that a part of the houses in Hamburg are built on piles, and that the

soil is in many places below the level of the water of the river, it would be very marvellous if a town thus disadvantageously situated were so admirably drained. In any case, the engineers in charge of the Hamburg sewage works make no such pretensions. On the contrary, they informed one of our representatives that the main sewers were originally intended to drain the ground and therefore were not impervious, but had purposely been made to leak; that the sewers were built of bricks; that there was no natural fall; that the sewage had to be raised artificially by pumping; and that, to drain satisfactorily, there were many districts where the ground on which houses are built should be raised artificially. Worse than all this, there is no system of inspection to ensure that all drains and waste-water pipes are properly trapped and disconnected from the sewers. Great as is the undoubted importance of the question of water-supply, a treatise on cholera at Hamburg which does not deal with these and other grave sanitary defects is certainly open to the charge of being somewhat one-sided.

If Professor Koch ignores the sanitary defects of Hamburg he does not fail to point out the sanitary defects of the Nietleben Asylum. This is perhaps even more surprising, for, though evidently conscious of these potent causes of disease, he lays no stress upon them and would appear to regard them as of but little importance. Thus we are told that the asylum was built in 1840. What knowledge existed of sanitation in Germany, or, for the matter of that, in any other country, in 1840? Then we are told that the asylum has a sewage farm intended to treat the sewage of 600 persons, but that the asylum had 991 inhabitants. Among this population there were 122 cases of cholera, resulting in 52 deaths. This occurred during the winter, and there was no reservoir at the sewage farm to retain the sewage during frosty weather. The sewage water, which was found to contain from 350,000 to 470,000 germs per cubic centimetre, was allowed to flow over the frozen ground without being properly filtered or purified. Attendants coming from Hamburg infected the sewage, the sewage infected the water-supply, the water-supply was not properly filtered, and therefore cholera broke out in the asylum, and this in a simultaneous manner all over the building, instead of creeping from ward to ward, as it had done in the 1850 and 1866 epidemics. Professor Koch further remarks, but again fails to lay stress on the fact, that the ward which suffered the most was that of the incurables, who were exceptionally dirty in their habits; while in Pavilion P—, which was only half full of inmates, no case occurred. All this would seem to show that the Nietleben Asylum is in an insanitary condition, which renders it especially susceptible to cholera influences, and that the worst parts of the asylum suffered most and the better parts least. Instead, however, of insisting on the necessity of better sanitation, Professor Koch suggests that the attendant at Pavilion P— was more careful in boiling the water given to the inmates. That some carelessness may have existed in some of the other pavilions is probable, but it is not probable that it prevailed in all these pavilions. Surely the water was carefully boiled in some of the pavilions where cholera prevailed. It would be a very peculiar coincidence if proper precautions were taken only in the pavilion where there was no overcrowding and which was only half occupied. Might it not have been the plentiful supply of space and air rather than the boiled water that saved the inmates in Pavilion P—, and might not Professor Koch be teaching a more useful lesson if he insisted on the necessity of plenty of room and of efficient ventilation? Again, in the neighbourhood of the asylum the cholera outbreaks seem to be associated with the drinking of the polluted water of the Saale river. We are told that at Trotha the disease was entirely restricted to one exceptionally insanitary house. This house was inhabited by 14 families, consisting of 62 persons, and some workmen who had drunk Saale water had cholera; but there was no cholera anywhere else at Trotha, and 16 or 18 persons died from the disease in this self-same unwholesome house during the 1866 epidemic. What, then, was the principal cause of cholera—the drinking of the Saale water or the living in this especially unhealthy and overcrowded house? Many persons drank Saale water and did not have cholera, but they did not live in such insanitary, overcrowded houses.

The same arguments apply to Hamburg and Altona. The facts are capable of being read differently and of receiving another interpretation than that which has been given to them. The prevalence of cholera varied, not according to the

water-supply, as Professor Koch would have us believe, but according to the density of the population, the foulness of the subsoil, and the poverty of the inhabitants. We are referred to the cholera maps, but we have seen and have published such maps and do not find that they coincide with the water-supply.¹ The spots marking places where deaths from cholera occurred become thinner and more scattered as we look on the Altona side of Hamburg; but this reduction of cholera cases commences within the boundaries of Hamburg, and before the frontier line of Altona is reached. Then, as we have pointed out several times before, there were far greater differences between the various districts of Hamburg itself, where the same water is drunk, than there is between Altona and Hamburg. It seems very conclusive to state that at Altona the Elbe water was filtered and the death-rate from cholera was only equal to 2·13 per 1000, whilst at Hamburg the Elbe water was not filtered and the death-rate from cholera was equal to 14·2; but these are mere generalisations, and sanitation has to deal essentially with details. We should like to know—unfortunately we do not know—what was the death-rate in those few portions of Altona which can be compared with Hamburg. They would probably be found to correspond much more closely with the experience acquired at Hamburg; for it was precisely in the low-lying and worst-drained districts of Altona that most of the Altona cases of cholera occurred. It is preposterous to compare the part of Altona built on a dry hill with Hamburg, built on marshy soil. But even taking the figures of Altona as a whole, which is a manifestly unfair thing to do, we find that in Hamburg itself, in districts that almost touch Altona, the Rotherbaum and Harvestehude districts, the mortality from cholera was 5·91 and 4·43 per 1000 inhabitants. But in these districts the average income is 2310 marks and 3155 marks; they are the wealthiest districts of Hamburg. The income of the two districts actually touching Altona is very low—563 marks for Eimsbüttel and 421 marks for St. Pauli, yet their death-rates from cholera were 10·76 and 12·56. Perhaps these death-rates are below the Hamburg average because these districts, being the nearest to Altona, possess something of the sanitary advantages enjoyed at Altona. As we get further away from these a reference to the map we published will show there is a higher death-rate even where there is a higher income—for instance, in one such district, 17·52 per 1000 deaths from cholera, though the average income is 668 marks per inhabitant. In fact, poverty alone does not produce a high death-rate; it must be in combination with bad sanitary conditions. All this, however, Professor Koch passes over; in his mind Altona and Hamburg only differ inasmuch as they have different water supplies. He forgets also that this difference, even in respect to the water-supply, did not always exist. In 1831 the water was probably just as bad at Altona as at Hamburg, yet the death-rate from cholera at Altona was only 0·5 per 1000, while it was equal to 3·4 at Hamburg. Altona enjoyed the same immunity in the 1866 epidemic, the figures being 5·4 for Hamburg and 1·4 for Altona. There is nothing new in the fact that in serious epidemics Altona is comparatively free from cholera, and that this immunity is due to other causes than water-supply is unconsciously hinted by Professor Koch. Not a word is mentioned as to the presence of the comma bacillus in the Hamburg water-supply during the great epidemic of 1892, yet the terrible fatality of this epidemic is attributed to this water-supply. On the other hand, speaking of the few cases of cholera that occurred at Altona during the following winter, Professor Koch says that "cholera germs—that is, cholera bacilli—were found in the water of the Elbe just below Hamburg and in the water of the Altona waterworks before filtration"; and as at that time two of the filter beds were out of order he thinks the germs got through these beds. Nevertheless, only a very few cases of cholera occurred. Nor is this the only instance of the bad water drunk at Altona. We are told that at Altona 366 wells were examined in May, 1892, and 92 were found to be polluted. One of the wells which was then considered good afterwards became polluted, and is supposed to have caused a small epidemic in the "Lange Jämmer" court. Thus the water drunk at Altona is not always filtered water free from cholera germs, and yet Altona enjoys a much greater immunity from cholera than Hamburg. Doubtless a polluted water-supply will cause an epidemic to spread with greater rapidity, and no one denies the extreme

importance of securing a pure water-supply; but there is a danger that a work such as that written by Professor Koch may tempt many local authorities to neglect other matters that are also of very great importance. For instance, at Hamburg great energy has been displayed since the epidemic in establishing filtering beds and waterworks, so that now the water at Hamburg is as good as at Altona; but the narrow, dark, unventilated courts and slums remain untouched. The leaky defective drainage is not remedied, the trapping of the soil pipes is not enforced, and the overcrowding of unhealthy dwellings continues as before. Complete protective measures against cholera have not yet been enforced. There might have been better results from the terrible lesson of 1892 if Professor Koch had not contented himself with a dissertation on the effects of water in cholera epidemics, but had dealt with equal fulness with the other causes which are quite as evident and which urgently need to be removed.

A PARISIAN EXHIBITION OF HYGIENE.

THE law of July 10th, 1894, compels all householders in Paris to connect their drains with the public sewers; but as all the sewers are not yet in a sufficiently perfect condition to receive the drainage of houses the connexion has only to be effected after notice has been served on the householders and within three years of the serving of such notice. According to the progress made in the building or repairing of sewers a fresh list of streets where such notices are to be served will be drawn up every year. The list for this year is of formidable length, and if within three years all the houses in these streets are properly drained Paris will be a much healthier town. There are actually in Paris 5447 blocks of buildings out of about 80,000 that are properly drained. These figures suffice to show how much work remains to be done. It is calculated that it will require ten years before all the cesspools and the portable pails &c. in Paris are replaced by properly flushed and trapped drains communicating directly with the sewers. The householders will have to pay a drainage tax instead of having, as at present, to pay a contractor to come and remove their pails or empty their sewers. In many cases the tax will be so much less than what is actually paid to the contractor that the economy realised will represent the interest and amortisation of the cost the householders will incur in building closets and drains suitable to the new system of drainage. Thus this great reform will have been brought about without imposing extra burdens on the already highly taxed population of Paris.

But the great majority of Parisian householders have no knowledge whatsoever of the proper methods of draining a house into a sewer. Till quite recently it has always been illegal to drain into sewers. For this reason the various syndical chambers representing the trades interested—plumbers, hardware manufacturers, paviors, &c.—have met together and obtained the sanction of the Government to hold an Exhibition of Hygiene at the Palace of the Liberal Arts, one of the wings of the great exhibition building of 1889. The leading sanitary reformers in France have been invited to help, and have consented on the condition that they should have the right to decide as to who should be admitted to exhibit and the right to exclude all bazaar elements and exhibits that are devoid of merit. Under these conditions a scientific committee of control and management has been formed, consisting, among others, of Dr. Brouardel, Dean of the Paris Faculty of Medicine; Dr. A. J. Martin, Director of the Sanitary Services of Paris; M. Bechmann, chief engineer of the town of Paris; and M. Louis Masson, chief sanitary inspector of Paris; and Messieurs Napias, Cornil, Proust, Bertillon, Gariel, Philbert, and others are also members of the committee, and their well-known names are a guarantee that every effort will be made to render the Exhibition in every sense worthy of its purpose. That purpose, as already explained, is to show the Parisian householder how he is to trap, flush, and ventilate. In this it was thought that English manufacturers, sanitary engineers, and plumbers might, advantageously to themselves, constitute an important British section. But the Exhibition is to open on May 15th or June 1st, and the time is wanting to bring exhibitors from abroad, though the exhibition professes to be international. However this may be, all measures that are

¹ THE LANCET, Aug. 25th, 1894.

likely to extend the knowledge of the practical application of the laws of health in their relation to domestic hygiene cannot but prove a benefit to the populations concerned. We therefore wish the Parisian Exhibition of Hygiene every success.

THE HIGH WYCOMBE CASE OF SCARLET FEVER.

A CASE of great interest, not only to the medical profession but to the public at large, has recently been decided at the Guildford County Court. The facts which came out in court are briefly these. Mr. Bird of High Wycombe was charged with exposing Sara Williams, a nurse suffering from a dangerous infectious disorder. Dr. Browne was also charged with the same offence, and the nurse was charged with having exposed herself while suffering from an infectious disease. Miss Williams was sent by the Hanover Institute for Nurses to attend upon the children of Mr. Bird, who were suffering from scarlet fever. A few days after her arrival she complained of not feeling well, and Dr. Browne saw her on Jan. 18th and expressed the opinion that she was developing scarlet fever. Thereupon it was decided that she should go to Woking, where the institute to which she belonged had a cottage used as a "quarantine" station. She accordingly travelled by train to Paddington, crossed London in a cab to Waterloo, where she sat some time in the waiting room, and then proceeded by train to Woking, there being other passengers in the compartment. On arrival at Woking the rash was well out. It was mentioned in court that it had been alleged that Mr. Bird had literally turned the nurse out when she was very ill; but we are glad to say that no evidence to support this was forthcoming, and the contradiction which he was of course unable, being a defendant, to give to the report from the witness box Mr. Bird has since made in the local papers. We learn that he has paid his fine and refused to carry the matter to a higher court. The cases against Dr. Browne and the nurse were dismissed. Another point to which we wish to draw attention is that, according to Mr. Wellington Lake's evidence, the Notification Act is not in force at High Wycombe, nor is there an isolation hospital there. On Jan. 18th a meeting of the Wycombe town council was held, when Mr. Wood moved that the Notification Act should be adopted. To this very sensible proposal one councillor remarked that the medical officer was paid to do the work, and yet he wanted some one else to tell him and "collar the half-crown." After sundry other remarks the resolution was put and lost by 12 votes to 7. We are sorry for this exhibition of ineptitude, for it is just conduct of this sort that helps to keep alive the old and, in most cases we fancy, now quite unjust allegation that vestries and town councils are incapable of doing any useful work or of treating any serious matter in the way it deserves. The Local Government Board will, we hope, impress upon the council the need of taking some definite steps to prevent the spread of infectious disease, and point out that a remedy lies ready to their hand if only they will use it.

This prevalence of diphtheria, which in its earlier days went by other names, is discussed at great length from the etiological point of view. Dr. Low came to the conclusion from a detailed investigation as to the general sanitary circumstances of houses and surroundings that faulty arrangements had not been commonly associated with occurrences of diphtheria, whilst the disease invaded dwellings where no fault could be found with the sanitary arrangements. As to emanations from sewers and drains which were locally credited with the disease, no evidence was forthcoming to show that this was the case. Water, as such, and defective flushing of hand-flushed and hence dirty closets, had also been credited with causing the disease, but Dr. Low is obliged to dismiss them after examination of all the circumstances. There seemed to be some concurrence between scarlet fever and diphtheria, but it was of limited extent; diphtheria, indeed, attained its greatest maximum in 1892, whereas scarlet fever prevailed most in 1893. But as has so often happened, a number of persons who were sent to the borough sanatorium with scarlet fever were attacked by well-marked diphtheria during their convalescence; and it is quite evident from the statistics of the hospital that there must have been a considerable amount of overcrowding there whilst the two diseases were simultaneously under treatment. In July, 1893, this was especially so, and "bad throats," some in a "sloughy" and "phagedenic" condition, were the result. This cannot be claimed as "isolation" work, which is the primary duty of a sanitary authority as regards hospital provision. Many other conditions influencing diphtheria are discussed in the report, but since 1890, at least, the disease had been so far prevalent that its cause could hardly be looked for beyond the limits of the borough where sources existed sufficient to explain the operation of personal infection. A seaside resort runs special risks as to importation, but Hastings seems to have retained its infection with some tenacity, and this partly owing to the inadequate and very imperfect means of isolation which the town possesses. The outbreak of small-pox in Hastings in 1894 is dealt with at length, but we pass rapidly over the clearly written statement as to this and limit ourselves to a few statistical considerations only. From January to June, 1894, there were 86 cases of small-pox in the registration district—namely, 37 in the urban and 49 in the rural district. Definite information was obtained as to the vaccination of 79 out of the 86 cases, the remaining 7 being doubtful. Two amongst the latter had died, and others had been so covered by confluent disease that nothing could be made out as to vaccination. The deaths at all ages amongst the 67 vaccinated was at the rate of 4.4 per cent.; it was 33 per cent. amongst the 12 unvaccinated. Under ten years of age there was no death amongst the vaccinated, whereas 4 out of 10 children under ten who were unvaccinated died. Out of the 67 vaccinated cases 35 were mild, 8 severe, and 3 very severe. Out of the 12 unvaccinated 1 was mild, 5 severe, and 4 very severe. Around the small-pox hospital 7.1 per cent. of 70 persons living within a hundred yards circle were attacked; whereas on infinitely larger populations the incidence dwindled gradually down to 0.2 per cent. when a zone of from 400 to 500 yards' distance from the hospital was reached.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6317 births and 4751 deaths were registered during the week ending March 30th. The annual rate of mortality in these towns, which had declined in the three preceding weeks from 35.0 to 27.7 per 1000, further fell last week to 23.4. In London the rate was equal to 21.1 per 1000, while it averaged 25.0 in the thirty-two provincial towns. The lowest rates in these towns were 14.5 in Swansea, 15.1 in Cardiff, 16.5 in Birkenhead, 16.8 in Croydon, and 17.8 in Halifax; the highest rates were 30.8 in Manchester, 36.6 in Brighton, 37.1 in Bolton, 38.3 in Wolverhampton, and 42.4 in Burnley. The 4751 deaths included 311 which were referred to the principal zymotic diseases, against 302 and 315 in the two preceding weeks; of these, 101 resulted from whooping-cough, 63 from measles, 53 from diphtheria, 45 from diarrhoea, 26 from scarlet fever, 23 from "fever," and not one from small-pox. No fatal case of any of these diseases occurred last week in Portsmouth; in the other towns they caused the lowest death-rates in Cardiff, Leicester, Leeds, and

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

Diphtheria and Small pox at Hastings. by Dr. BRUCE LOW.¹—This report deals separately with a prevalence of diphtheria and an outbreak of small-pox in Hastings, the former relating mainly to 1893 and 1894, and the latter to the early part of 1894. In the Hastings registration district there were 40 deaths from diphtheria in 1892, and 41 in 1893; and including deaths from other allied throat diseases there were during the three years 1891-93 no less than 177 such fatalities.

¹ Eyre and Spottiswoode, East Harding-street, E.C.; John Menzies and Co., Edinburgh and Glasgow; Hodges, Figgis, and Co., Grafton-street, Dublin. Price 1s.

Bristol; and the highest rates in Sheffield, Manchester, Gateshead, and Bolton. The greatest mortality from measles occurred in Bolton and Sheffield; from scarlet fever in Wolverhampton; whooping-cough in Plymouth, Salford, Blackburn, and Gateshead; and "fever" in Halifax and Sunderland. The 53 deaths from diphtheria included 31 in London, 3 in West Ham, 3 in Manchester, 2 in Liverpool, and 2 in Birmingham. No fatal case of small-pox was registered in London or in any of the thirty-two large provincial towns. There were 58 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, March 30th, against 56, 57, and 58 at the end of the three preceding weeks; 11 new cases were admitted during the week, against 8, 12, and 11 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1555 against 1619, 1615, and 1587 on the three preceding Saturdays; 161 new cases were admitted during the week, against 141, 133, and 184 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had declined from 1336 to 740 in the three preceding weeks, further fell to 497 last week, but were 48 above the corrected average. The causes of 74, or 1.6 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Cardiff, Nottingham, Oldham, Sunderland, and in eight other smaller towns; the largest proportions of uncertified deaths were registered in Portsmouth, Birmingham, Salford, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined in the three preceding weeks from 42.8 to 31.3 per 1000, further fell to 25.4 during the week ending March 30th, but exceeded by 2.0 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 18.4 in Greenock and 22.3 in Perth, to 32.0 in Paisley and 34.2 in Leith. The 732 deaths in these towns included 35 which were referred to measles, 26 to whooping-cough, 14 to diarrhoea, 5 to scarlet fever, 5 to diphtheria, 3 to "fever," and 2 to small-pox. In all, 90 deaths resulted from these principal zymotic diseases, against 110 and 115 in the two preceding weeks. These 732 deaths were equal to an annual rate of 3.2 per 1000, which was 1.7 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 48 and 56 in the two preceding weeks, declined again to 35 last week, of which 15 occurred in Glasgow, 9 in Leith, and 6 in Aberdeen. The 26 deaths referred to whooping-cough were within one of the number recorded in the preceding week, and included 12 in Glasgow, 6 in Leith, and 4 in Dundee. The fatal cases of diphtheria, which had been 6, 4, and 9 in the three preceding weeks, declined to 5 last week, of which 2 occurred in Glasgow. The deaths from scarlet fever, which had been 10 and 5 in the two preceding weeks, were again 5 last week, of which 3 occurred in Glasgow and 2 in Aberdeen. The 2 fatal cases of small-pox were registered in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 385 and 313 in the two preceding weeks, further declined to 189 last week, but were 83 above the number in the corresponding week of last year. The causes of 38, or more than 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 42.5 and 45.0 per 1000 in the two preceding weeks, further rose to 48.6 during the week ending March 30th. During the thirteen weeks of the quarter ending on Saturday last the death-rate in the city averaged 37.1 per 1000, the rate during the same period being 26.0 in London and 30.5 in Edinburgh. The 326 deaths registered in Dublin during the week under notice showed an increase of 24 upon the number in the previous week, and included 12 which were referred to the principal zymotic diseases, against numbers declining from 14 to 7 in the three preceding weeks; of these, 4 resulted from "fever," 3 from whooping-cough, 3 from diarrhoea, 1 from small-pox, 1 from diphtheria, and not one

either from measles or scarlet fever. These 12 deaths were equal to an annual rate of 1.8 per 1000, the zymotic death-rate during the same period being 1.6 in London and 4.0 in Edinburgh. The 4 deaths referred to different forms of "fever" exceeded by 2 the number in the preceding week. The fatal cases of small-pox, which had been 5, 4, and 5 in the three preceding weeks, declined to 1 last week, a lower number than in any week since November last. During the first three months of the current year no fewer than 78 deaths from small-pox have been registered in Dublin. The 326 deaths in the city last week included 46 of infants under one year of age and 112 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a further increase upon those recorded in recent weeks. Two inquest cases and 3 deaths from violence were registered; and 103, or nearly a third, of the deaths occurred in public institutions. The causes of 25 or nearly 8 per cent., of the deaths in the city last week were not certified.

THE HEALTH OF GREATER MANCHESTER.

THE corporation of Manchester have just issued a report on the health of Greater Manchester during the period 1891-3—that is, for the first three years that have elapsed since the recent extension of the city. The report, which is from the pen of Dr. Tatham of the General Register Office and previously for several years medical officer of health of Manchester, is in more than one respect a remarkable one. Whether regarded from the point of view of the statistician or from that of the practical sanitarian, we think that both its subject matter and the manner in which it is arranged are excellent, and quite typical of what such a work should be. We therefore propose to notice somewhat in detail those special features of the report which distinguish it from other productions of a similar character. It will be remembered that soon after the publication of the 1891 Census Reports Dr. Tatham compiled an elaborate series of Life Tables for Manchester, with the object of ascertaining by reliable methods, and of demonstrating the actual extent of the waste of human life which is occasioned by the notoriously unhealthy conditions prevailing in the older parts of the city. As these life tables were reviewed in our columns at the time of their publication we need refer to them here only so far as is necessary to explain the object we have now before us—namely, that of giving publicity to Dr. Tatham's plan of applying life-table methods to the estimation of the efficacy of preventive operations, or, in the words of the report, his mode of using "the life table as a test of sanitary progress or regress."

Omitting the first eight pages of the report as chiefly of local concern, and coming to Part II., we find that this section has been written as practically a continuation of the remarks which accompanied the life tables of 1892 and 1893, which must therefore be considered as part of the present report. This section alone is so rich in matter of prime sanitary importance that to do it justice would occupy more space than is at our present disposal. We can only, therefore, touch upon a few leading points in the report and express the hope that as the work itself has been published by the corporation it will be carefully studied by those of our readers who are more especially interested in questions of sanitary reform. There is no need that we should reiterate our oft-repeated warning against the acceptance of crude death-rates alone as a sufficient test of the relative healthiness of populations variously constituted in regard to age and sex. The life table method, which eliminates errors dependent upon varied age constitution of populations, is obviously the only satisfactory basis of comparison between communities differently circumstanced, not only in this respect, but perhaps in regard to sanitary conditions also. The life table is the instrument by which alone the true significance of mortality can be gauged year by year, and thus the direction shown of changes taking place in the mortality at various ages. It is true that such comparison may be made, after a fashion, without the aid of a life table by simply comparing the death-rates at successive ages in one year with those in other years, and in the same way the death-rates in a given town in any year may be compared with those of England and Wales in the same year; but only a life table can show the combined effect of a higher rate at one age period and a lower rate at another, or can express the result thus produced on the duration of life at all ages and on the comparative duration of life in childhood, maturity, and old age.

Dr. Tatham has made it abundantly clear that the vitality of the population of Manchester, taken as a whole, compares very unfavourably with that of the population of England and Wales in the aggregate. It was, therefore, natural that in his recent endeavour to fully investigate the question he should inquire whether the whole of the city population is subject to similar adverse conditions or whether, as is more likely, the town is composed of sections differing widely in regard to the average lifetime of their inhabitants. For the purpose of testing this point two supplementary life tables were constructed in the year 1893, one for the old township of Manchester and the other for the outlying townships—i.e., the newer part of the city. In order that these two life tables might fairly represent the populations of the areas chosen it was found to be essential that the populations and the deaths of inmates in Manchester public institutions should be distributed to the townships to which they properly belonged. This was accordingly done. The results are sufficiently startling. We cannot give them here in full; but, as a rough measure of the loss of working power that is implied in the heavy mortality which is known to have occurred in the old township of Manchester, it may be mentioned that the survivors of each sex at the age of twenty-five years scarcely exceeded the numbers that should have reached forty-five years of age. In other words, the numbers who reached the threshold of this the most active and in many respects the most important vicennium of lifetime were equal only to the numbers that should survive to the end of that period. There can be no reasonable doubt that this heavy mortality in the earlier periods, the springtime of life, implies enfeebled vitality in the survivors, and that this is actually the case there is abundant evidence in the report before us.

We now have to consider Dr. Tatham's mode of applying the Manchester Life Table, to the calculation of what he has termed the life capital of the population. For the sake of convenience the whole term of life is divided into three stages, named respectively childhood, working period, and decline; and by the help of a formula given in the report the mean future life term of persons at each of these age groups is ascertained. This future lifetime is termed by Dr. Tatham the average working life capital of the population. A table is given which shows the application of the life tables to the existing population of Manchester. It proves that so long as the age constitution remains as it was at the last census enumeration, and the death-rates at the various ages remain as in the decennium 1881-90, the average life capital of the population of the old township of Manchester, taking young and old together, is only twenty-eight years, the ordinary annual expenditure of this capital being equal to $3\frac{1}{2}$ per cent. If, now, we calculate for any period the number of deaths that should have occurred in each age group at the rates of 1881-90 and compare them with the deaths which actually occurred during this period, the difference between the two sets of figures will be the number of lives saved or lost by the fluctuations of mortality in the given period, and by means of readily constructed tables we can ascertain the gain or loss of life capital due to these fluctuations of mortality. This has been done in the report, and the balance of loss and gain is shown for the three years 1891-93. It will be readily understood that the gain or loss of life capital depends not simply on the number of lives saved or wasted, but even more on the value of those lives to the community. For example, 100 lives of young adults who have, say, twenty-five years each of potential working life before them, are economically better worth preserving than would be the same number of persons in the decline of life who can never again hope to add to the sum of the common wealth. It is familiar knowledge to those who have studied the vital statistics of Manchester that a terrible waste of human life is constantly going on there, especially in the older parts of the city. The amount of this waste and its incidence at the various stages of life have been accurately measured and set before the constituted authority in the recent reports of Dr. Tatham. In the old township of Manchester there lives a population of more than 100,000 persons, who pay a tax which must be reckoned not in pounds, shillings, and pence, but in years, months, and days—a tax amounting, on the average, to fully 30 per cent. of the lifetime of every member of the community, and which presses so heavily upon their vitality that the men and women are known to enter the period of decline at an age when they ought scarcely to have passed the prime of life. It is pos-

sible, and indeed probable, that a part, and perhaps a considerable part, of the excessive mortality which afflicts these unfortunate people is inseparable from life and work in a great manufacturing city; but surely much remains to be done before Manchester can claim to have attained to the irreducible minimum. The task which lies before the authorities is that of restoring to every infant in Central Manchester the twelve years of life expectation of which it has been defrauded by the evil surroundings of its birth; and we cannot believe that the governing body of that great and opulent city will rest content until something considerable has been accomplished in the direction here indicated.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

THE following officers have arrived from India in the *Britannia*:—Surgeon-Colonel Markey, Surgeon-Majors McGill, Dodd, and Hughes, and Surgeon-Captain Young. Surgeon-Lieutenant-Colonel Harvie Scott will proceed from Aldershot to Dublin, and Surgeon-Major O'Sullivan from Dublin to Aldershot. Surgeon-Captain Skerrett has been posted to the North-West district, and Surgeon-Lieutenant-Colonel Robinson to Dublin. Surgeon-Major Bourke has been posted to Woolwich, and Surgeon-Major Pike to Belfast. Surgeon-Major-General Davis, who is about to retire, will be succeeded at Portsmouth by Surgeon-Colonel Markey on promotion.

INDIA AND THE INDIAN MEDICAL SERVICES.
